

Data -

- Data is a collection of information
- When data is processed it becomes information
- Data can be number, symbol, character or any kind info.
- The logical & meaningful form of data is called information.

Two types of Data type

- (1) Built in data type: int, float, char, double, which are defined by programming language.
- (2) User defined data type: User can define his own data type.

e.g. `typedef Struct Student`

`int Roll;`
`char name;`

`};`

`SS1;`

* Data object

→ is a set of elements such a
Set may be finite or infinite.

Ex. Set of students studying in
Second year of Computer Eng.
it's finite set,

Set of natural numbers is an
infinite set.

Structure

Def

A da
descrion
And Se
This trip
data stra

* Data Structure :

→ The combination which describe
the set of elements together
with the description of all legal
operations is called data structure.

* Abstract

The abstr
Set of d
A - Axior
to be e
now is

Ex:- The set of elements
as integer, and the operations
on integer are addition, subtraction,
multiplication, division, etc.

* Primitive

→ Primitive
mental
int, f

So, the data object - integer along
with description of these

structure.

Def

A data structure is a Set of domain \mathcal{D} , a set of function F , and set of axioms A . This triple (\mathcal{D}, F, A) denotes the data structure d . \mathcal{D} is Domain.

*

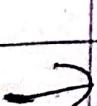

Abstract Data Type!

The abstract data type is triple of \mathcal{D} -Set of domain, F -Set of fun A-Axioms in which only what is to be done is mentioned but how is to be done is not mentioned

In ADT, cell implementation details are hidden.

*

Primitive and Non Primitive

Primitive data types are the fundamental data types.

int, float, double, char.

→ Non primitive data types can be built using primitive data types.

Ex:- Structure, Union.

Primitive Data Types

`int count;`

`float average;` ~~float off~~

`char choice;`

Linear

Array

Lists

Stacks

Non Primitive Data Types

tyedef Struct Student

`int roll_no;`

`float marks;`

`};`

→ Data structures modelling

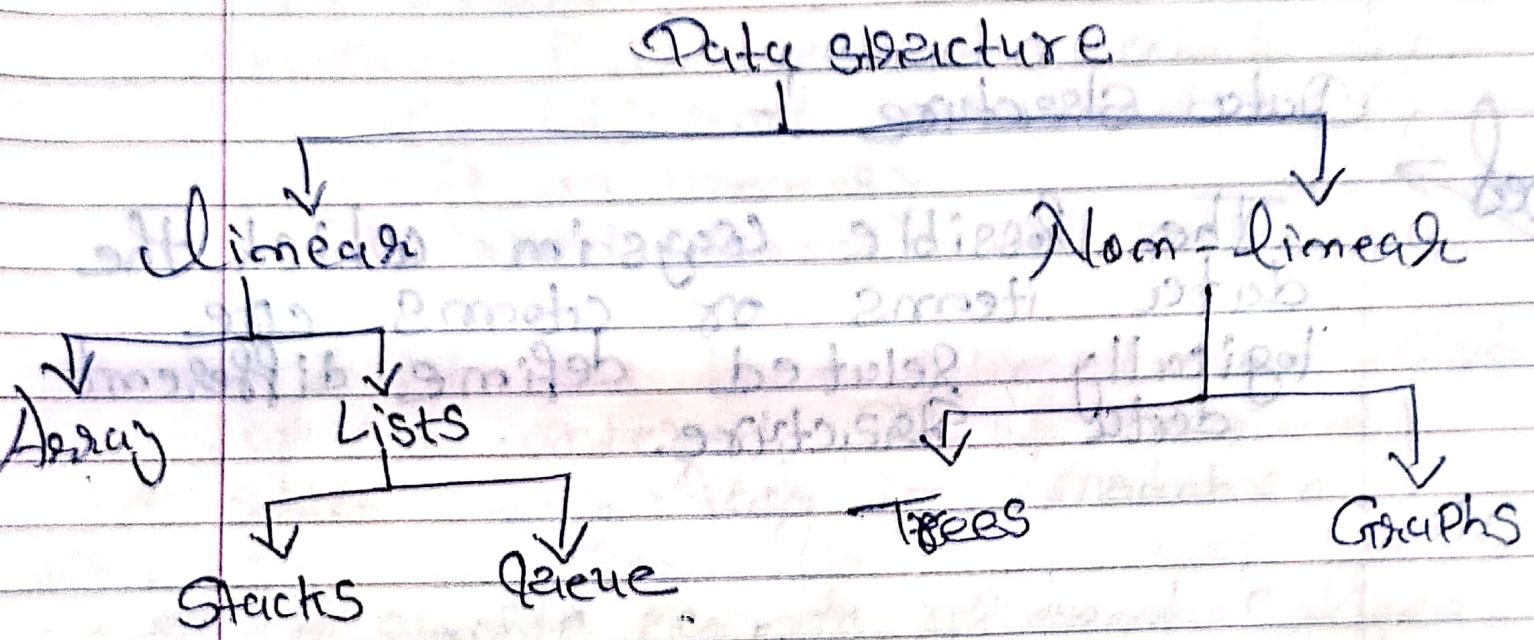

→ We can solve the data problem.

* Linear data

Structure is arranged in sequence

* Non-linear
those in which

* Types of Data Structure

- Data Structure is used for modelling the Problem
- We can apply some algorithm on the data structure to solve particular problem.

* Linear data Structures are the data structure in which data may be arranged in a list or in a straight sequence
Array, List

* Non-linear data Structure are those in which data may be arranged in

hierarchical structures.

trees, graphs

Data Structure :-

The possible ways in which the data items or elements are logically related define different data structure.

Link-List

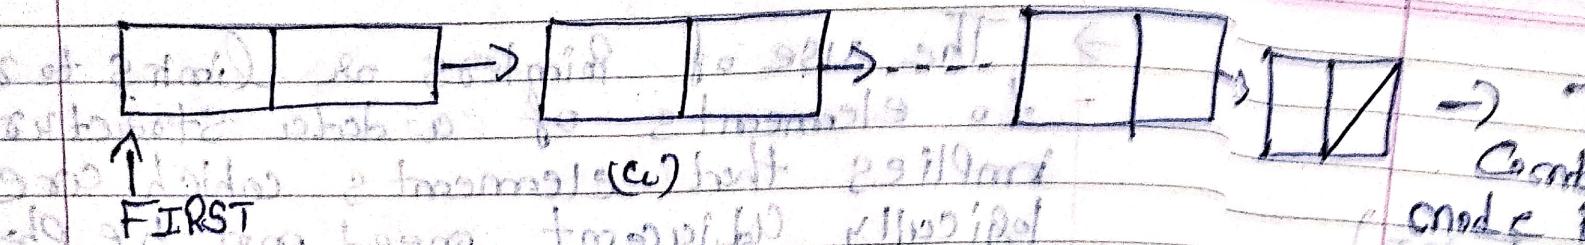

Page
Date

→ The use of pointers or links to refer to elements of a data structure implies that elements which are logically adjacent need not be physically adjacent in memory.

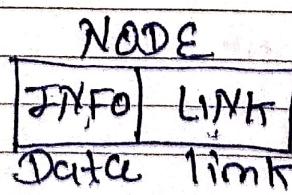

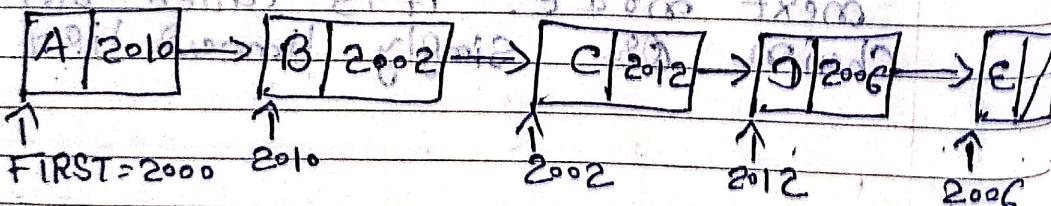

it is called linked allocation.

→ A list has been defined to consist of an ordered set of elements which may vary in members.

→ A simple way to represent a linked list is to expand each node to contain a link or pointer to the next node. it is called singly linked list.

- The variable `FIRST` contains the address or pointer which gives the location of first node of a list.
- Each node is divided into two parts.
- First part represents the information of elements, Second part contains the address of the next node.

- Available area of storage for this node structure consists of limited stack of available mode.

→ The Pointer Variable /AVAIL Contains the address of the top node in the Stack.

→ Address of the next available node is to be stored in the Variable NEXT.

~~defn:-~~ The linked list is a collection of nodes. Each node consists of two field 'data' & 'link'.

* Advantages

(1) Insertion and Deletion of elements can done efficiently.

(2) No wastage of memory.

Allocated & Deallocated memory easily.

* Disadvantages

(1) Does not support Random or Direct access.

(2) Each data field should be supported by link field to point to next node.

Simply linked list

Function INSERT (X, FIRST).

Given X, a new element

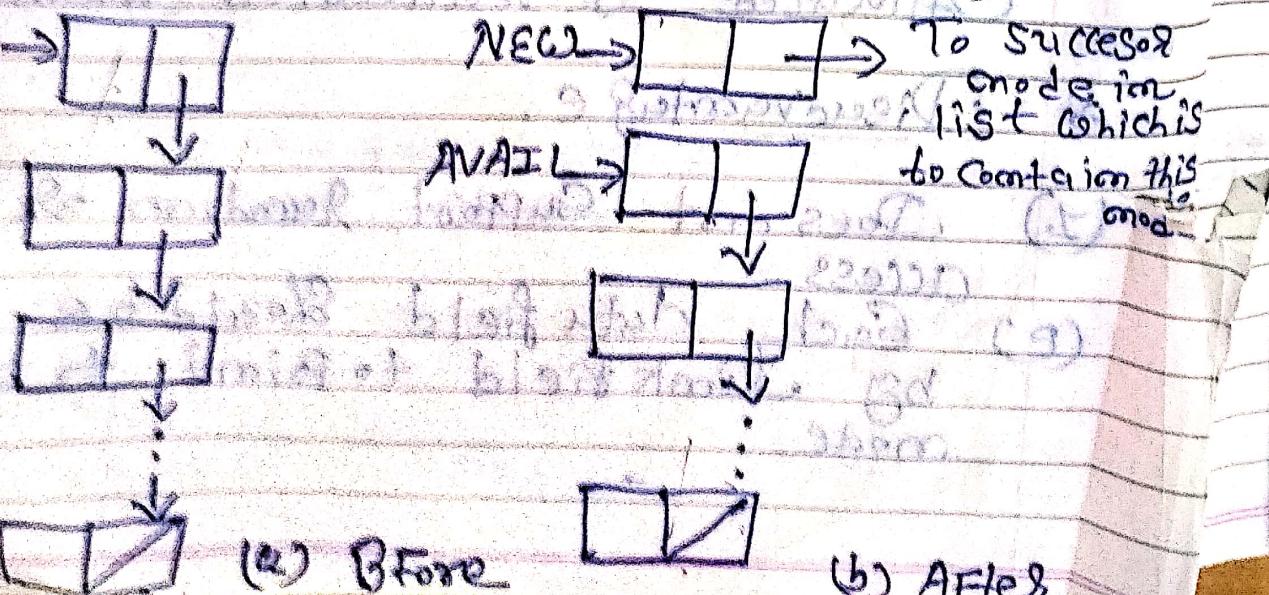

FIRST, a pointer to the first element of a linked list

to insertion in the list.

Element

AVAIL is a pointer to the top elements of the availability stack.

NEW is a temporary pointer variable. (Availability stack.)

* Insert the mode at first position

1. [Underflow]

if $AVAIL = NULL$

then write ('Availability Stack')

(Underflow)

(FIRST, X) Return (FIRST)

2. [Obtain address of next free mode]

$NEW \leftarrow AVAIL$

3. [Remove free mode from availability stack]

$AVAIL \leftarrow \text{LINK}(AVAIL)$

4. [Initialize fields of new mode
and its ~~the~~ link to the list]

$\text{INFO}(NEW) \leftarrow X$

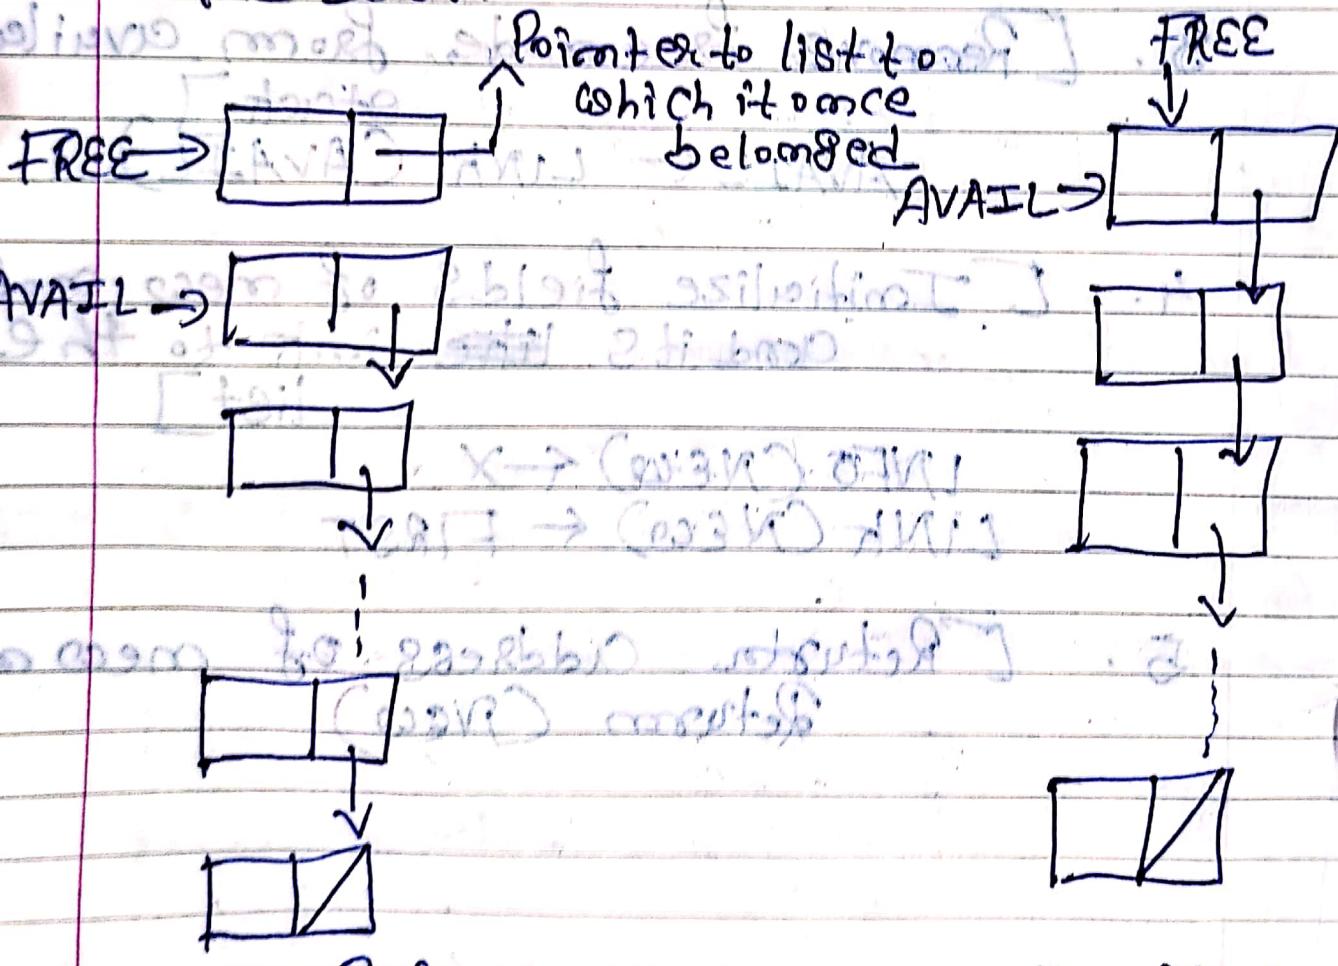

$\text{LINK}(NEW) \leftarrow FIRST$

5. [Return address of new mode]
Return (NEW)

* Insert the mode at last position.

function INSERT(x, FIRST)

Def NEW and SAVE Contiguous
Pointer Variables. It is required
that ITAN be inserted at the end of
the list.

(ii) Before

(b) After

Availability slack before and after a free mode has been return.

1. [Underflow?]

fail if $b \text{AVAIL} = \text{NULL}$
then write ("Availability Stack
(AVAIL) full → $b \rightarrow$ b)
Return(FIRST)

2. [Obtain address of next free
node]

$\text{NECO} \leftarrow \text{AVAIL}$

3. [Remove free node from
availability stack]

$\text{AVAIL} \leftarrow \text{LINK}(\text{AVAIL})$

4. [Initialize fields of new node]

$\text{INFO}(\text{NECO}) \leftarrow X_{\text{offfront}}$
 $\text{LINK}(\text{NECO}) \leftarrow \text{NULL}$

5. [IS the list empty?]

if $\text{FIRST} = \text{NULL}$
then Return(NECO)

6. [Initiate search for the
last node]

~~SAVE ← FIRST~~

7. [Search for end of list]
 Repeat while $\text{LINK}(\text{SAVE}) \neq \text{NULL}$
 $\text{SAVE} \leftarrow \text{LINK}(\text{SAVE})$

8. [Set LINK field of last mode
 from INFO to NEW]
 $\text{LINK}(\text{SAVE}) \leftarrow \text{NEW}$

9. [Return first mode pointer]
 Return (FIRST)

* Insert mode otherwise.

Function $\rightarrow \text{INSORD}(X, \text{FIRST})$

\rightarrow it is required that X be inserted so that it preserves the ordering of the terms in increasing order of their INFO fields.

1. [Underflow?]

[Test if $AVAIL = \text{NULL}$
 then write ('Availability Stack Underflow')
 Return (FIRST)]

2. [Obtain address of next free node]
 $NEw \leftarrow AVAIL$

3. [Remove node from the availability stack]
 $AVAIL \leftarrow \text{LINK}(AVAIL)$

4. [Copy information content into new node]

$\text{INFO}(NEw) \leftarrow X$

5. [Is the list empty?]

[Test if $FIRST = \text{NULL}$
 then $\text{LINK}(NEw) \leftarrow \text{NULL}$
 Return (NEw)]

6. [Does the new node precede all others in the list?]

if $\text{INFO}(NEw) \leq \text{INFO}(FIRST)$
 then $\text{LINK}(NEw) \leftarrow FIRST$

Return (NEW)

7. [Initialize temporary Pointer]

~~double (filling) () a file~~
~~Condition~~ $\text{SAVE} \leftarrow \text{FIRST}$

8. [Search for Predecessor of new mode]

Repeat while $\text{LINK}(\text{SAVE}) \neq \text{NULL}$
 and $\text{INFO}(\text{LINK}(\text{SAVE})) \leq \text{INFO}(w)$

~~Finalize filling~~
~~(JAVA)~~ $\text{SAVE} \leftarrow \text{LINK}(\text{SAVE})$

~~LINK (SAVE) ← NEW~~

9. [Set link field of new mode
 and its Precessor]

~~X → (var) (var)~~

$\text{LINK}(\text{NEW}) \leftarrow \text{LINK}(\text{SAVE})$

$\text{LINK}(\text{SAVE}) \leftarrow \text{NEW}$

10. [Return First mode Pointer]

~~(var)~~ $\text{Return} (\text{FIRST})$

* Delete the node from linked-list.

(DELETE(x , FIRST))

→ TEMP is used to find the desired node, and PRED keeps track of the Predecessor of TEMP.

1. [Empty list ?]

If $FIRST = NULL$

then write ('UNDERFLOW')
Return.

2. [Initialize Search for x]

$TEMP \leftarrow FIRST$

3. [Find x]

Repeat thru Step 5 while
 $TEMP \neq x$ and $LINK(TEMP) \neq NULL$.

4. [Update Predecessor marker]

$PRED \leftarrow TEMP$

5. [Move to next node]

$TEMP \leftarrow LINK(TEMP)$

6. [End of the list ?]

If $TEMP \neq x$

and then Delete ('NODE NOT FOUND')

Return

7. [Delete x]

if $x = \text{FIRST}$ (Is x the first node?)

then $\text{FIRST} \leftarrow \text{LINK}(\text{FIRST})$

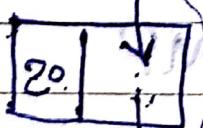

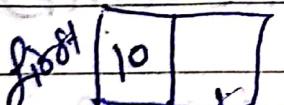

else $\text{LINK}(\text{PREV}) \leftarrow \text{LINK}(x)$

8. [Return node to availability area]

$\text{LINK}(x) \leftarrow \text{AVAIL}$

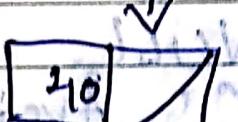

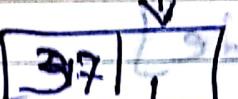

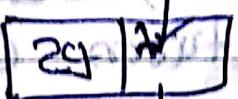

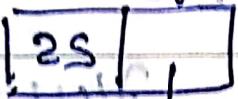

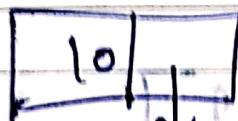

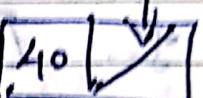

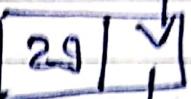

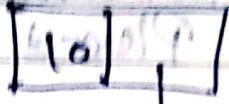

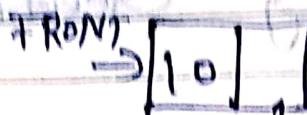

$\text{AVAIL} \leftarrow x$

Return

* Construction of a linked list.

FRONT → [29] ↗

* Copy Node in linked list.

COPY (FIRST)

→ This function makes a copy of this list.

→ The New list is to contain nodes chosen in formulation and pointer field removed by field and P.L.

FIELD & PTR.

→ The address of the FIRST node in the newly created list to be passed in.

BEGIN, NEW, SAVE and PREV are pointed variables.

Return (BEGIN)

The Circular linked list

mode

Replacing the null pointer in the last mode of a list with the address of its first mode. Such a list is called a Circular linked linear list or Circular list.

Advantages

- Is concerned with the accessibility of mode. In circular list every mode is accessible from a given mode.
- We can easily delete the mode.

* Disadvantages

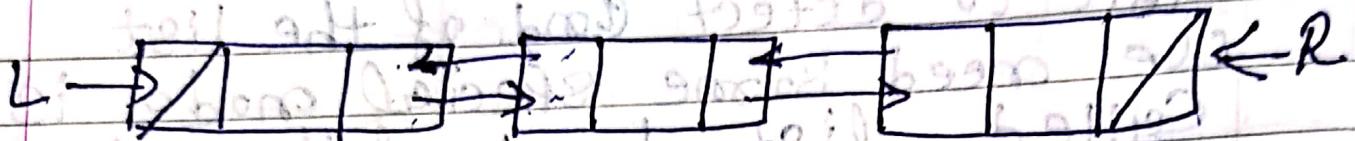

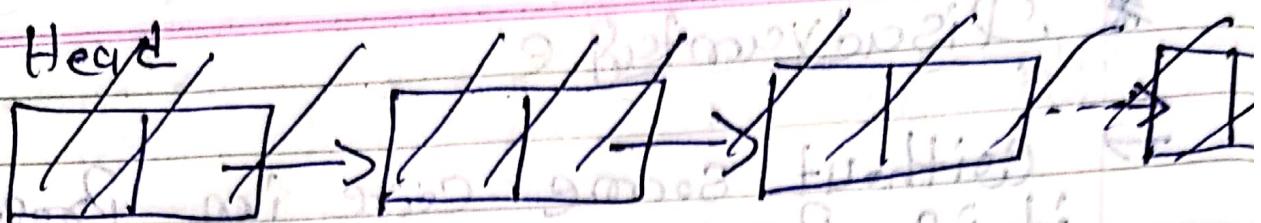

→ Without some care in processing, it is possible to get into an infinite loop. It is important that we are able to detect end of the list. We need some special node is called list head of the circular list.

Doubly linked - linear list

→ The link are used to denote the predecessor and successor of a node. The link denoting the predecessor of node is called left-link. And denoting its successor is right link.

A list containing this types of node
is called a doubly linked linear
list or two-way chain.

Head

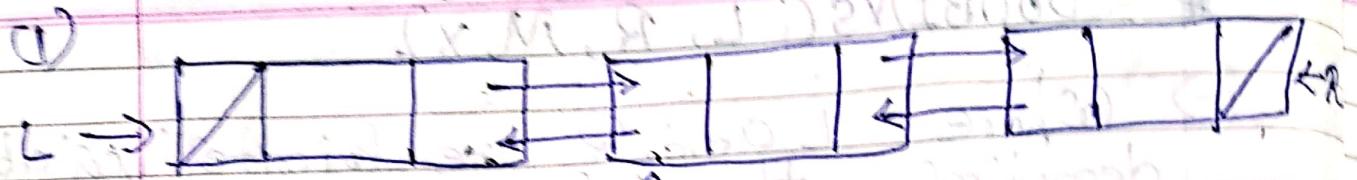

A doubly linked list.

- Where `lptr` and `rptr` are Pointed variable denoting the left-most and right-most node in list.
- The left-link of left-most node and the right-link of the right-most node are both `NULL`, indicating the end of the list for each direction.
- The left & Right links of a node are denoted by the Variable `L PTR` and `R PTR`.

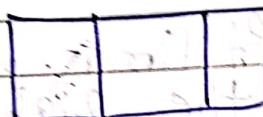

* Insertion in Doubly ^{Page} Linked List.

* DOUBINS(L, R, M, X).

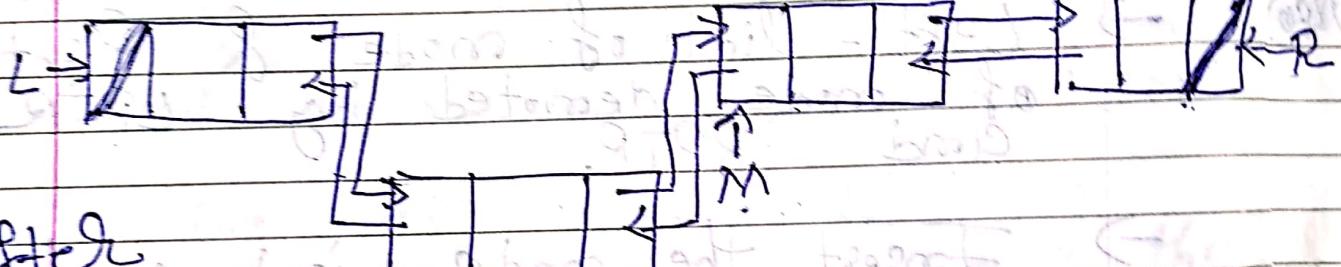

- Where L and R are Pointer Variable denoting the left-most and right-most node in the list.
- The left link of the left-most node and the right link of the right-most node are both NULL it indicating the end of the list for each direction.
- Left-link of node & Right link of node denoted by LPTR and R PTR.
- Insert the node into a doubly linked list to the left of a specified node whose address is given by variable M.
- NEGO is the address of the new node being inserted.

8. $\text{head} \rightarrow 1 \rightarrow 2 \rightarrow 3 \rightarrow 4 \rightarrow 5 \rightarrow \text{head}$

* Difference between linked-list and Array.

Link-List

Array

→ The link-list is a collection of nodes and each node is having some data field and next link field

The array is a collection of similar datatypes elements. the data is always stored at some index of the array.

10	20	30	40	50
----	----	----	----	----

a[0] a[1] a[2] a[3] a[4]

→ Any element can be accessed by sequential access only. Any element can be accessed randomly.

→ Physically the data can be deleted

only logical deletion of data is possible.

→ Insertion & deletion of data is easy. Deletion of data is difficult.

→ Memory allocation is dynamic. Memory allocation is static.

~~* Diff. bet on Simply & Doubly linked-list.~~

Simply linked-list

Doubly linked list

→ is a collection of nodes and each node is having one data field and one next link field.

Data	link
------	------

is a collection of nodes and each node having one data field, one previous link field and one next link field.

Previous	Data	Next
link		link

- The element can be accessed using next link.
 - No extra field is required. mode take less memory.
 - less efficient to access to elements.
- The elements can be accessed using both links
- One field is required to store previous link mode take more memory.
- More efficient access to elements.

* Application of linked-list.

- Representation of Polynomial and performing various operation such as Addition, mul And Evaluation on it.
- Performing addition of long positive integers.
- Representing non integer and non homogeneous list.

$$2 + x^5 + x^8 = p^3$$

$$8 + x^8 + x^5 = q^3$$

* link list Application for quadratic equation addition.

→ link-list used for list for representing quadratic eqn.

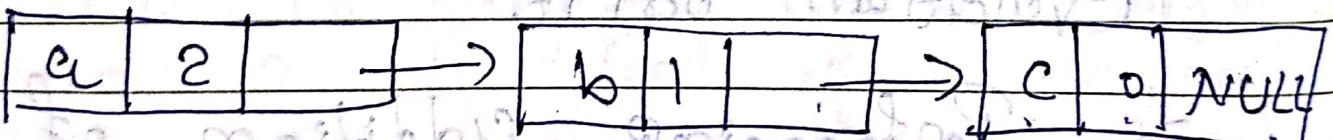

Struct Quad_EQ

```

int Coeff;
int exp;
Struct Quad_EQ *next;
};
```

Struct Quad_EQ *EQ1, *EQ2, *EQ3;

Graphically Any quadratic eqn can be represented using linked list.

$$a_2x^2 + b_1x + c_0$$

Consider

$$\begin{aligned}
 EQ_1 &= 3x^2 + 2x + 5 \\
 EQ_2 &= 7x^2 + 3x + 8
 \end{aligned}$$

Given two quadratic eqns. We can perform their addition as

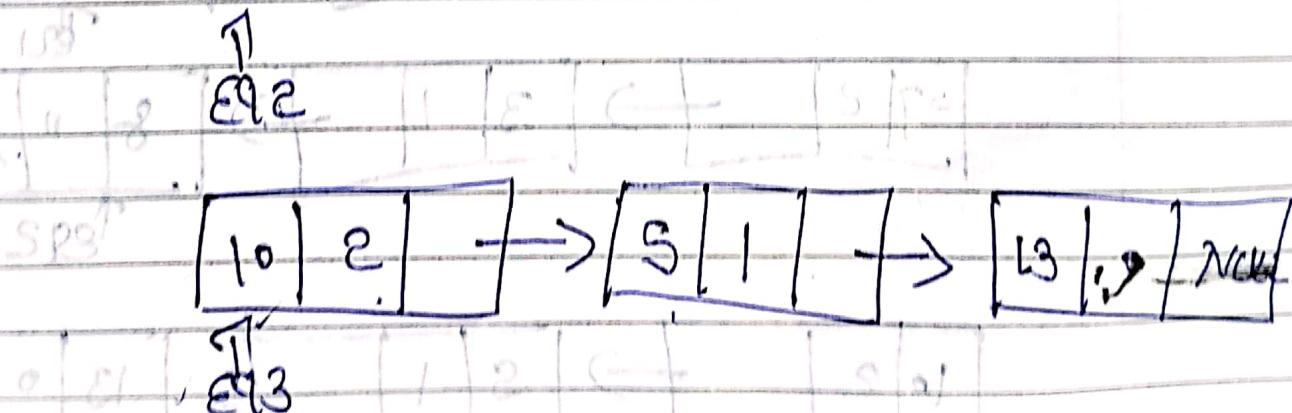

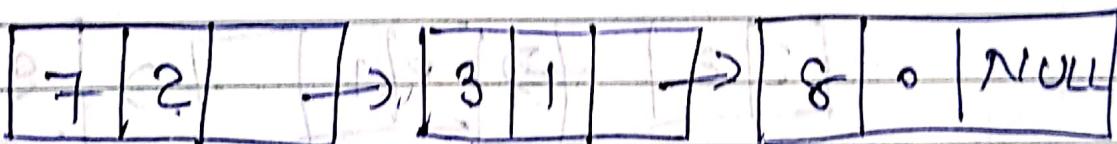

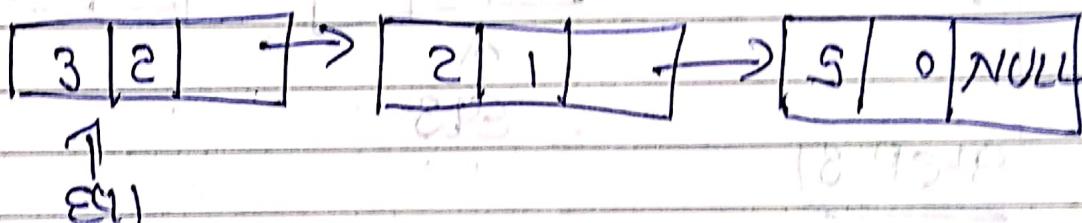

$$3x^2 + 2x + 5$$

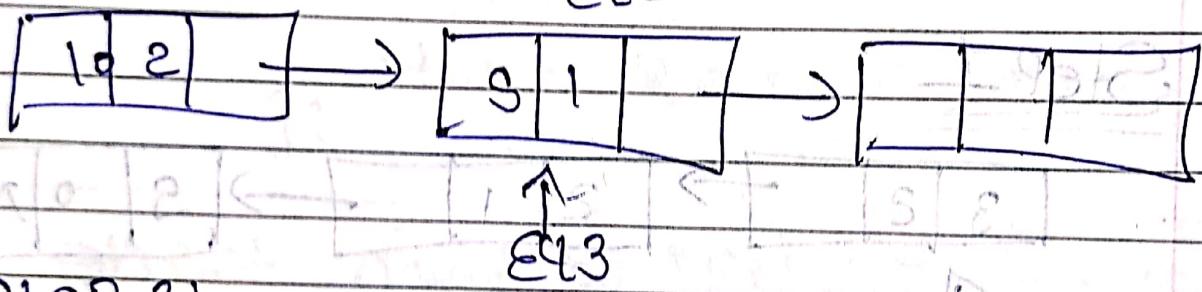

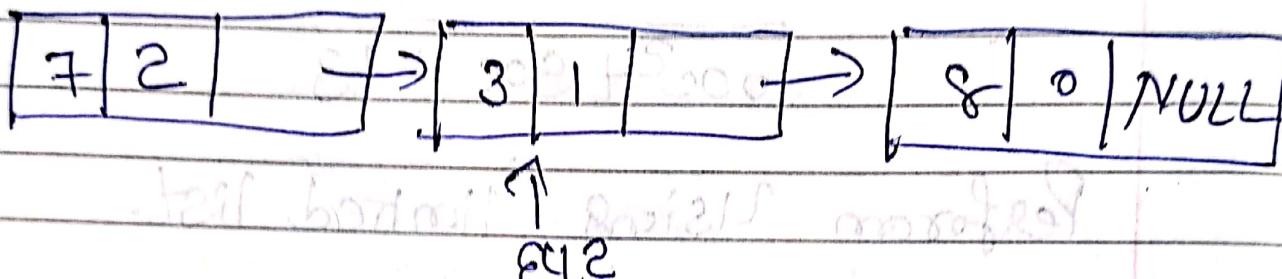

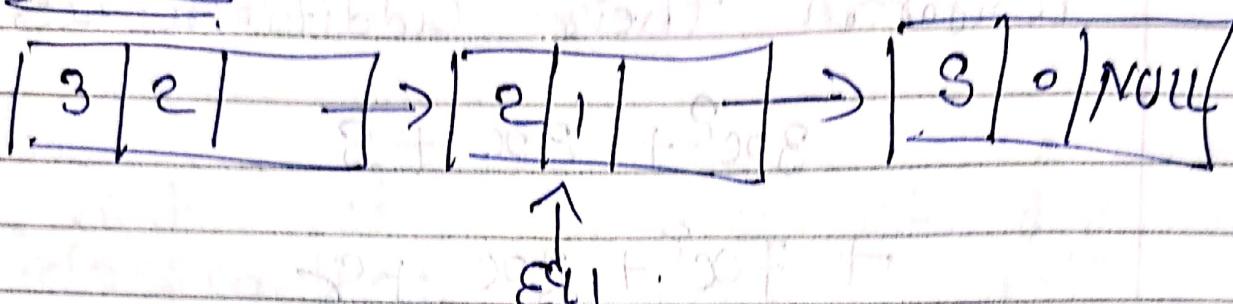

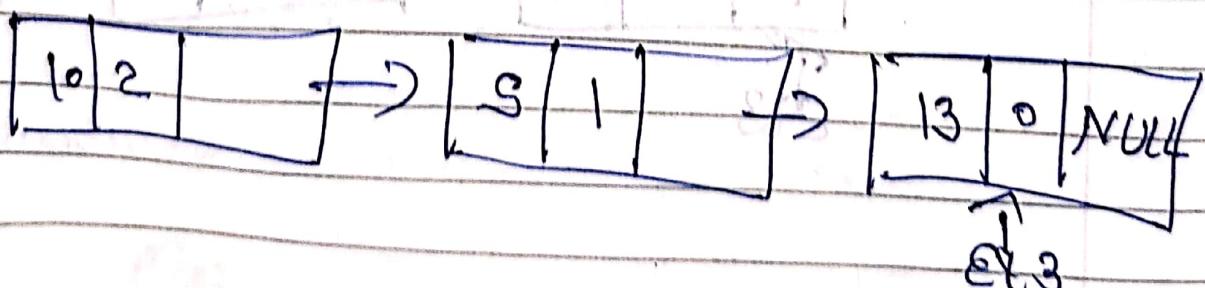

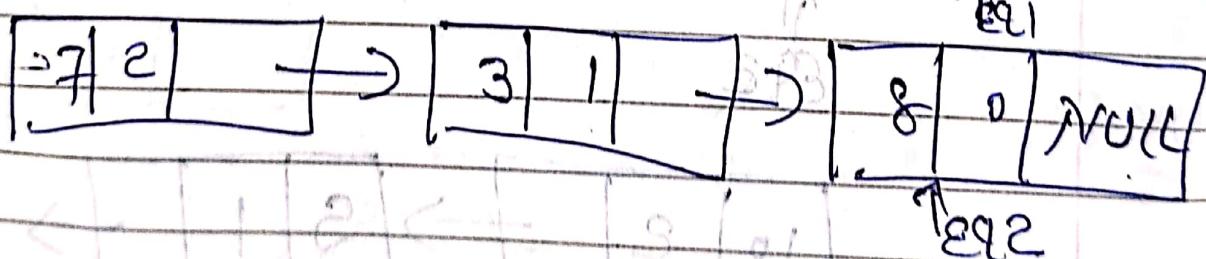

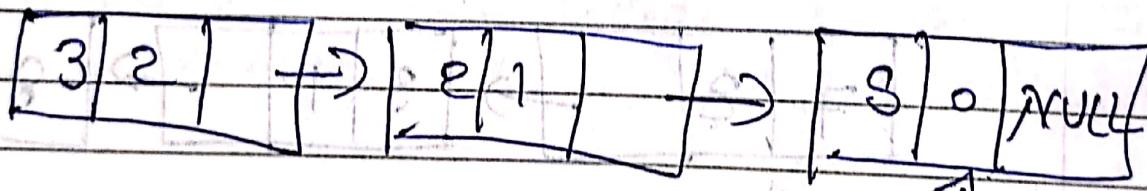

$$+ 7x^2 + 3x + 8$$

$$\hline 10x^2 + 5x + 13$$

Perform using linked list.

Step 1

Step 2Step 3)

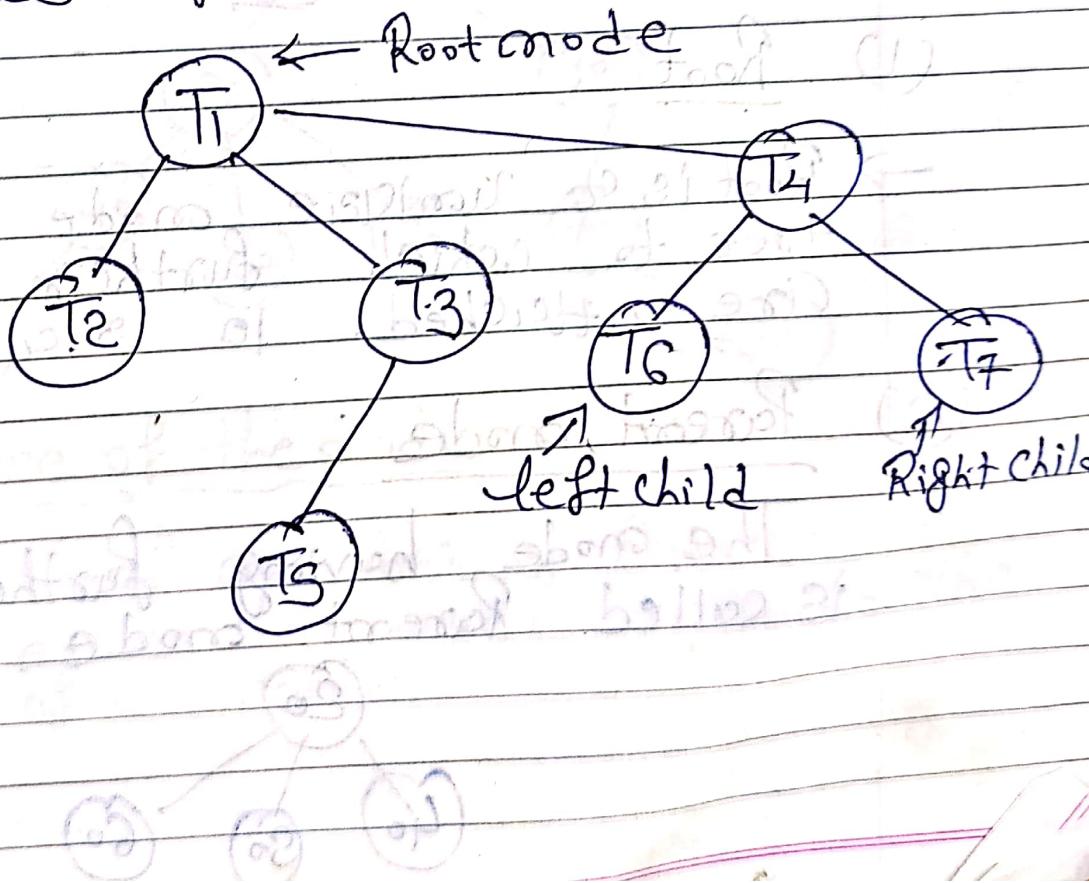

~~#~~ Trees

Page
Date

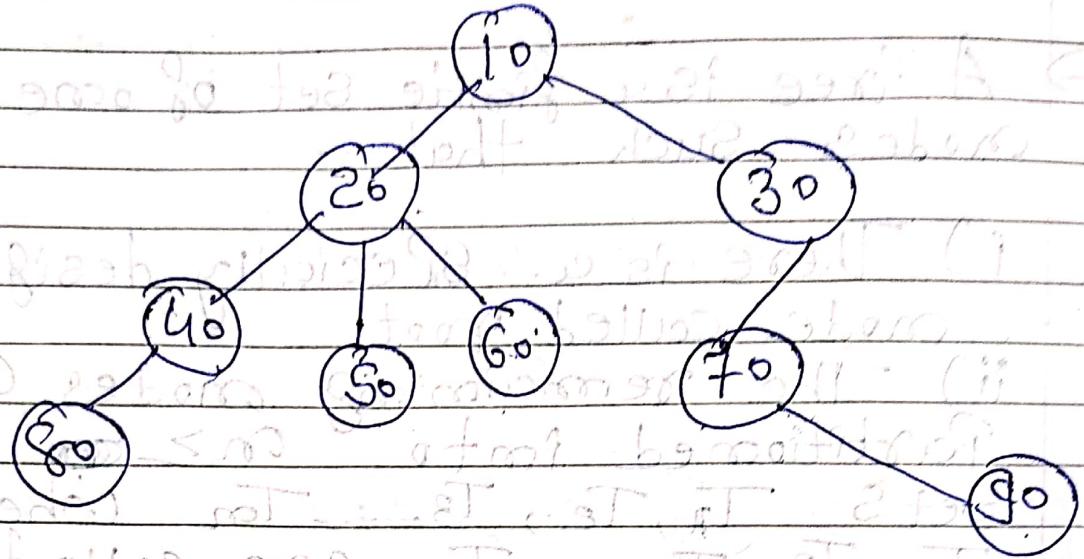

* Definition and concepts

→ A tree is a finite set of one or more nodes such that —

- i) There is a specially designed node called root.
- ii) The remaining nodes are partitioned into $m \geq 0$ disjoint sets $T_1, T_2, T_3, \dots, T_m$ where $T_1, T_2, T_3, \dots, T_m$ are called the subtrees of the root.

Basic Definitions

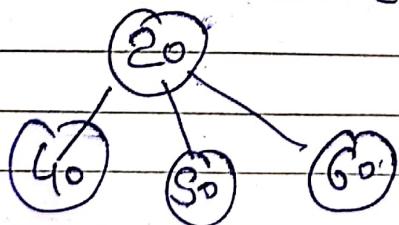

(1) Root

→ Root is a unique mode in the tree to which further subtrees are attached. 10 is a root mode.

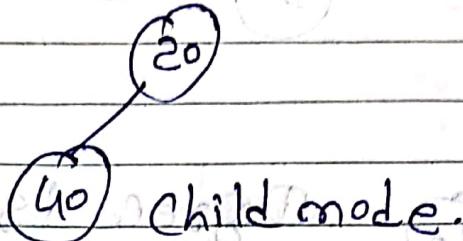

(2) Parent mode

The mode having further subbranches is called Parent mode.

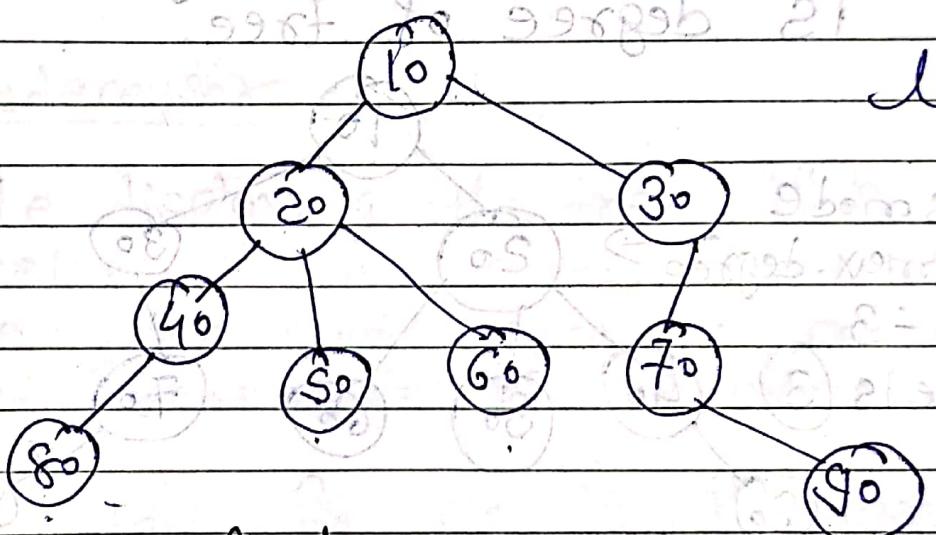

(3) Child nodes

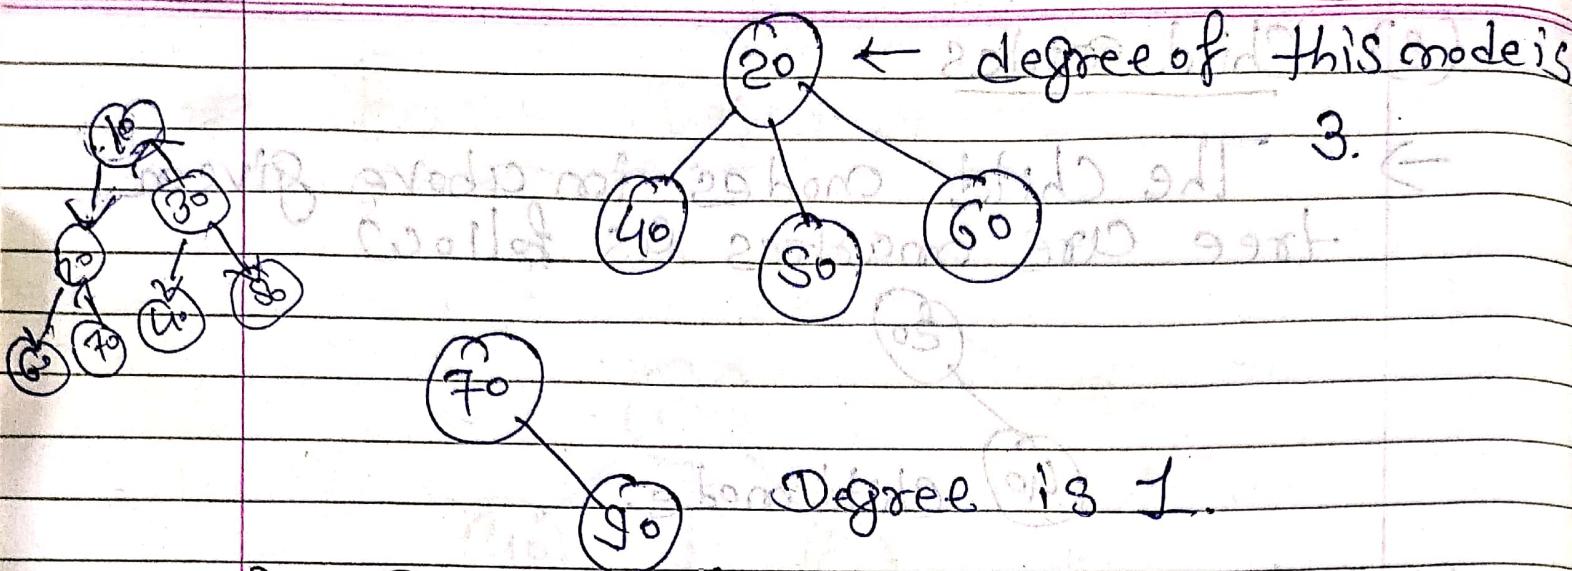

→ The child nodes in above given tree are marked as follows

(4) Leaves

These are the terminal nodes of the tree.

(5) Degree of the node

The total number of subtrees attached to that node is called the degree of a node.

(6) Degree of tree

The maximum degree in the tree is degree of tree.

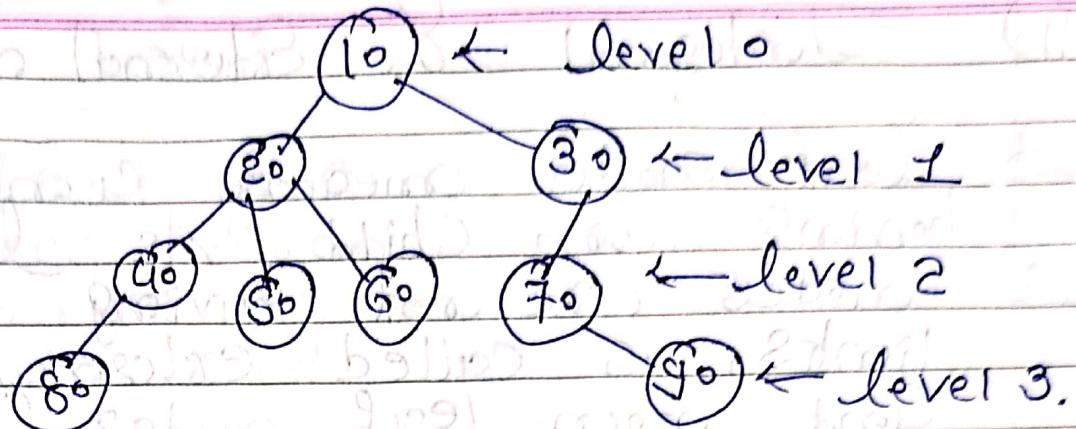

This mode with max. degree is - 3.

So degree is 3.

(7) Level of the tree

The root node is always considered at level zero.

The adjacent nodes to root are supposed to be at level 1 and so on.

(8) Height of the tree.

The maximum level is the height of the tree. Also called (depth) of tree.
 In above fig. height is 3.

(9) Predecessor

→ while displaying the tree, if some particular mode occurs previous to some other mode then that mode is called Predecessor of the other mode.

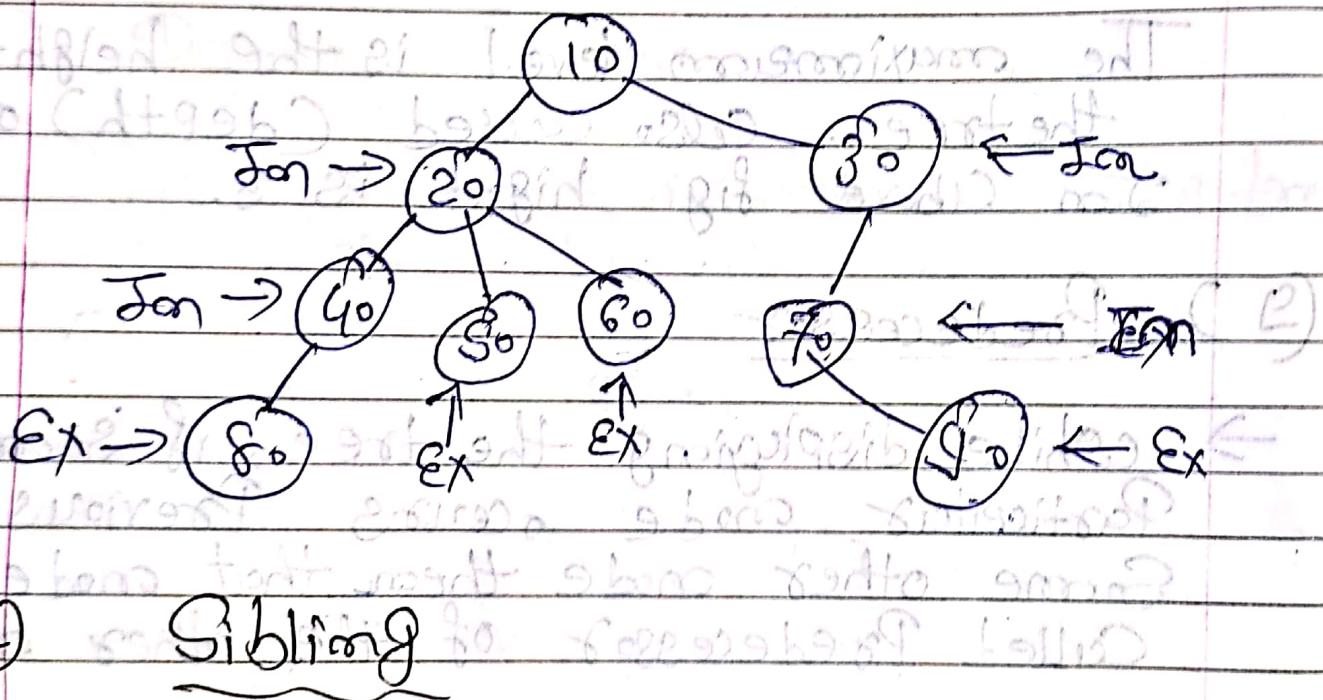

In above fig. 20 is Predecessor of 40.

(10) Successor

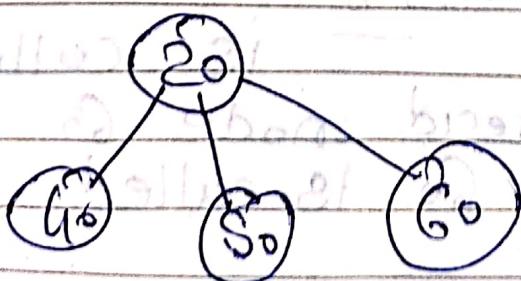

is called next mode.
 if we read mode 50 after reading 20 then 50 is called Successor of 20.

(11) Internal & External nodes.

→ leaf mode means a mode having no child. As leaf modes are not having further links, is called external modes and non-leaf modes are called internal mode.

(12) Sibling

The nodes with common Parent are called Siblings or brothers

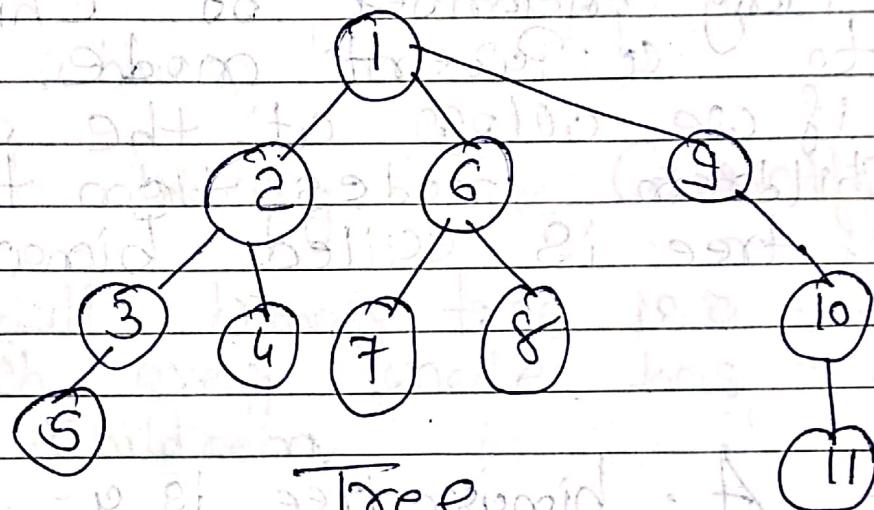

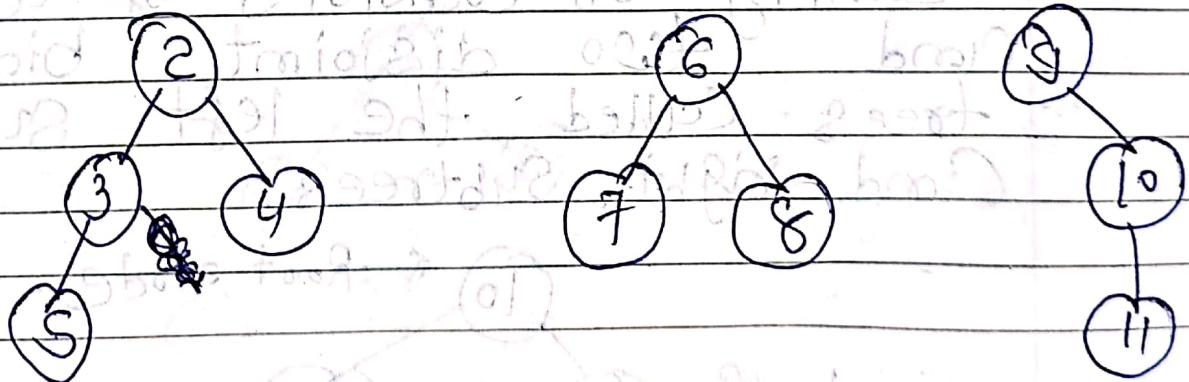

40, 50 & 60 are sibling mode

(13)

Forest

→ Forest is a collection of disjoint trees. From a given tree if we remove its root then we get a forest.

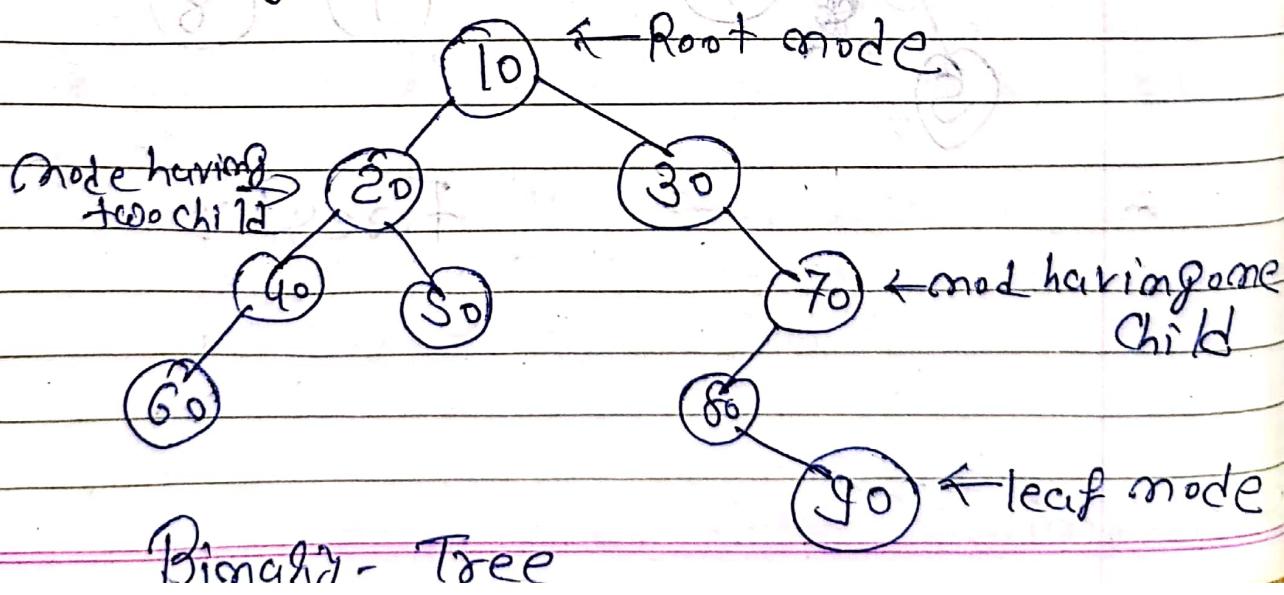

TreeForest

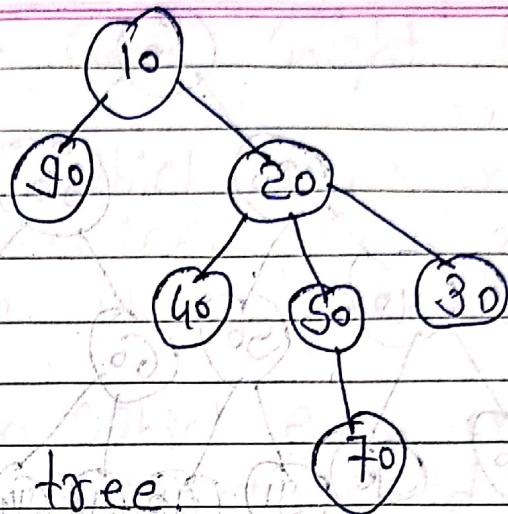

* Concept of Binary Trees.

~~Binary trees.~~

- In this trees, we can have any number of child nodes to a parent node.
- if we allow at the most two children nodes then that type of tree is called binary tree.

Def A binary tree is a finite set of nodes which is either empty or consists of a root and two disjoint binary trees called the left subtree and right subtrees.

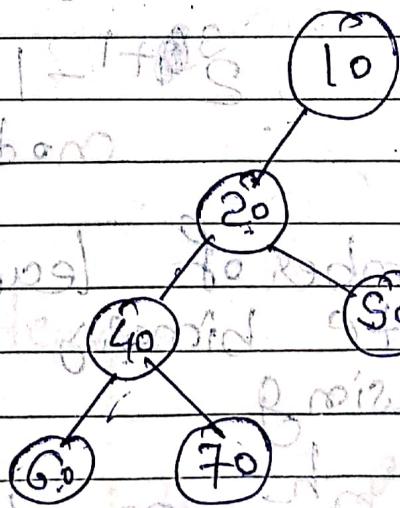

Not a binary tree.

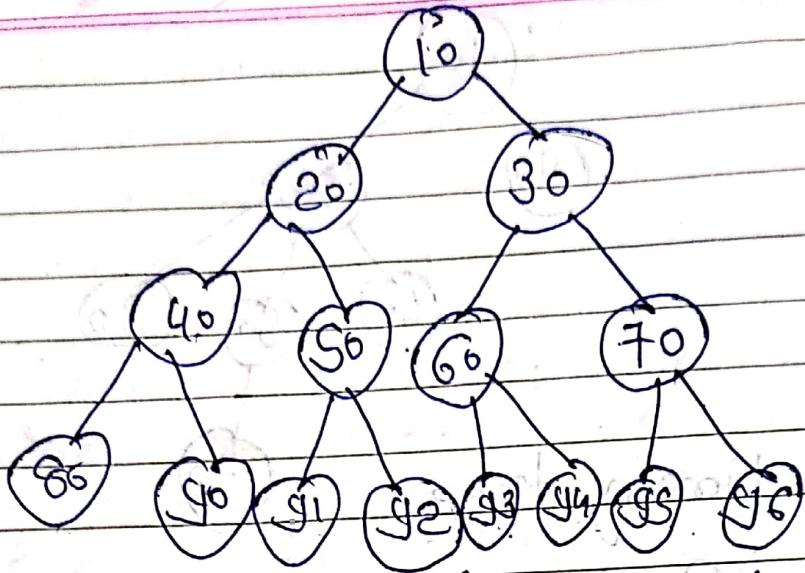

~~2 marks~~ ~~Full Radford~~ ~~strictly binary tree~~

~~2 →~~ A full binary tree is a tree in which every node has zero or two children.

~~* 2 marks~~ Complete Binary Tree.

~~2 →~~ A complete binary tree is full binary tree in which all leaves are at the same depth.

→ The total number of nodes in a complete binary tree are $2^h - 1$ where h is a height of the tree. In above fig.,

$$\text{height is } 3 \quad 2^3 - 1 = 8 - 1 = 15 \text{ nodes in the tree}$$

→ The number of leaf nodes in a complete binary tree can be found using

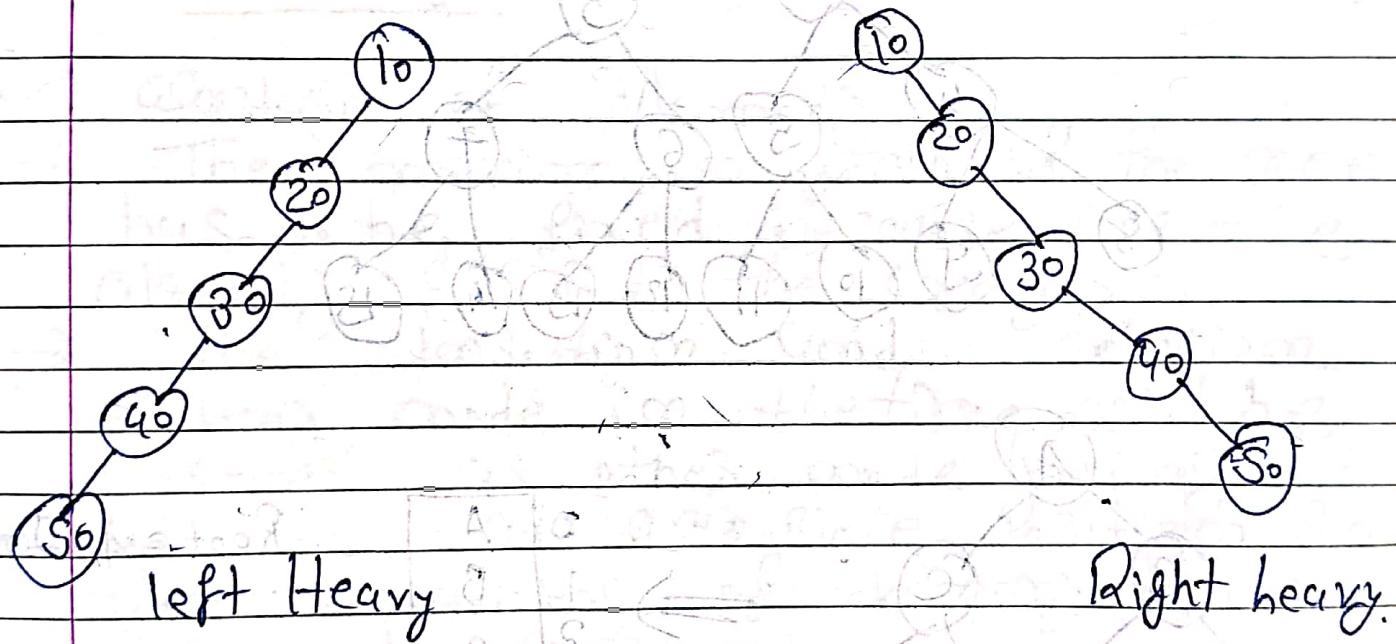

$$m = 2^h \text{ on total No. of leaf node}$$

h is height of binary tree.

$$h = 3 \quad 2^3 = 8 \text{ mode is leaf mode}$$

* Left Heavy and Right Heavy Trees.

- The tree in which each node is attached as a left child of Parent mode then it is left heavy tree.
- The tree in which each node is attached as a right child of Parent mode then it is called right heavy tree.

* Representation of Binary Tree -

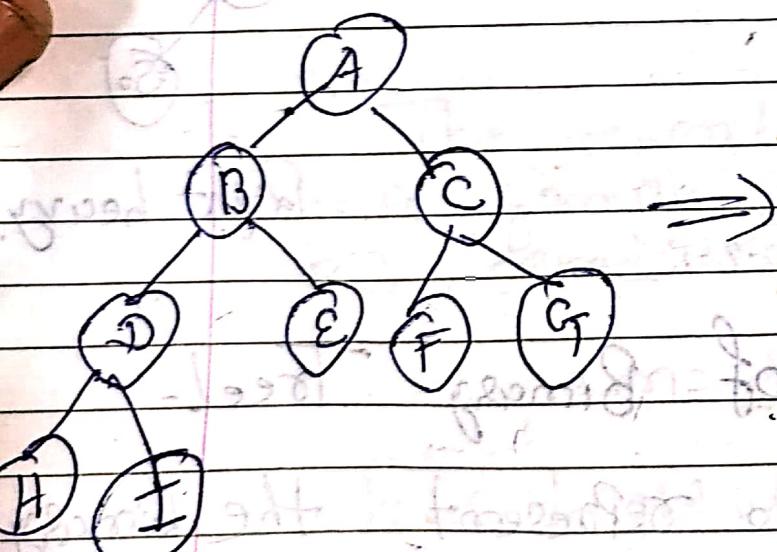

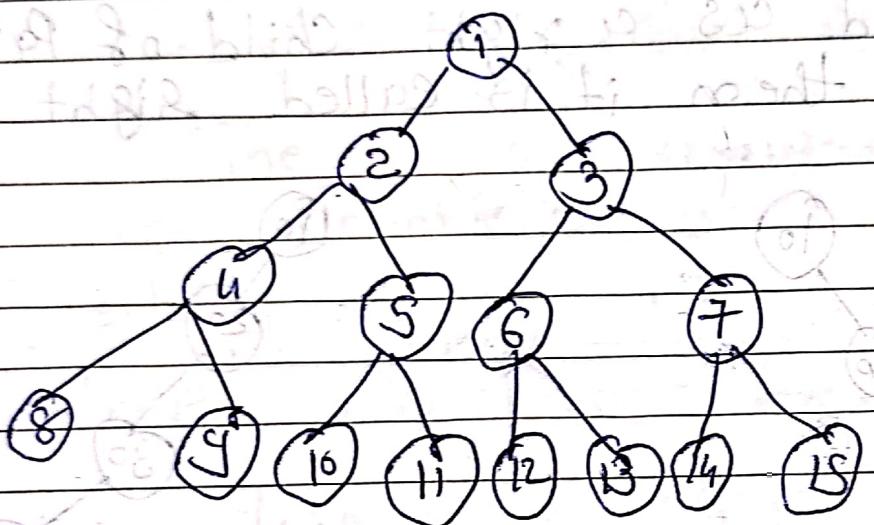

- Two ways to represent the binary tree.

- (1) Sequential representation.
- (2) Linked

(1)

Sequential or Array representation of tree.

→ Each node is sequentially arranged from top to bottom and from left to right.

0	A
1	B
2	C
3	D
4	E
5	F
6	G
7	H
8	I

Root = A = Index 0

Advantages

- The direct access to any mode can be possible and finding the Parent, left or right children of any particular mode is fast because of the random access.

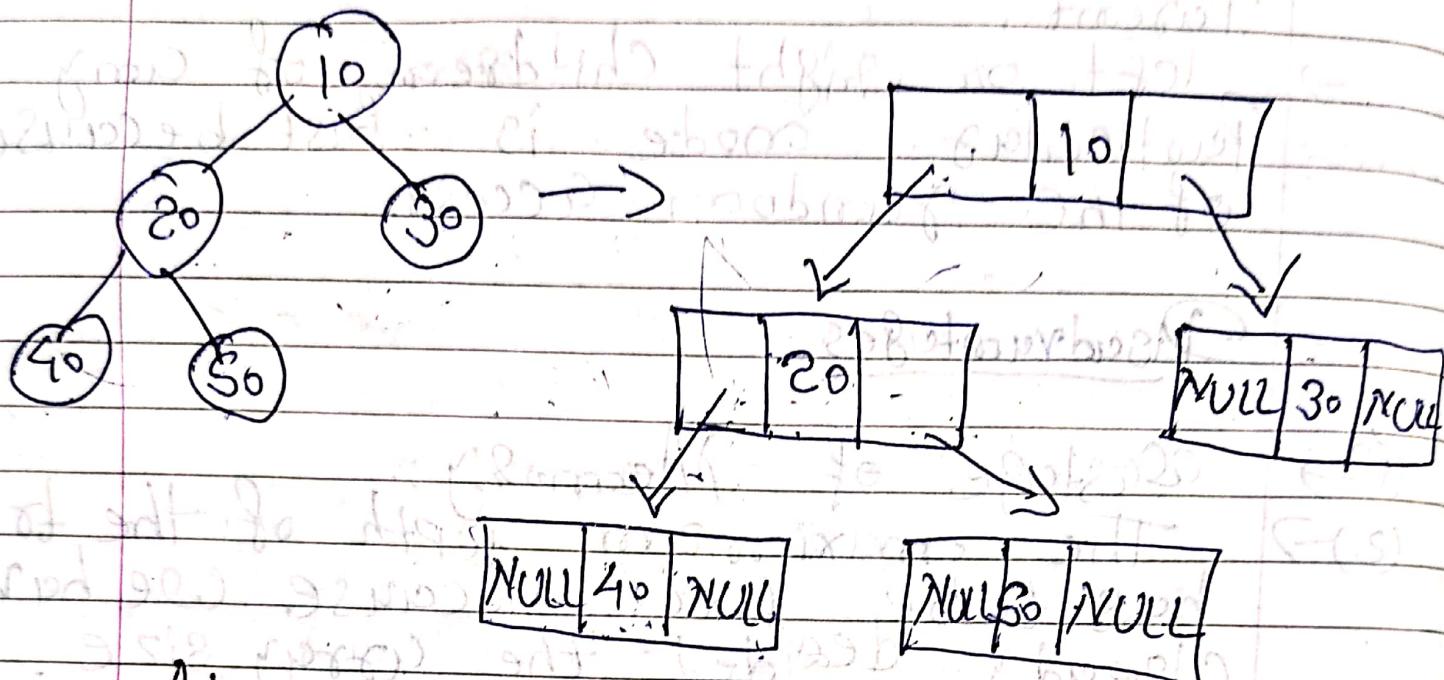

Disadvantages

- (1) → wastage of memory.
- (2) → The maximum depth of the tree has to be fixed because we have already decided the carry size.
- (3) → The insertion and deletion of any mode in the tree will be costlier as other mode having to be adjusted at appropriate position so that meaning of binary tree can be preserved.

* Limited representation of mode representations of binary trees.

A binary tree each mode will have left child, right child and data field.

left child	Datee	Right child
------------	-------	-------------

Advantages

- No wastage of memory.
- Insertions and deletions which are the most common operations can be done without moving the other nodes.

Disadvantage

- This representation does not provide direct access to a node and special algorithm are required.

→ This representation needs additional space in each node for storing the left and right sub-trees.

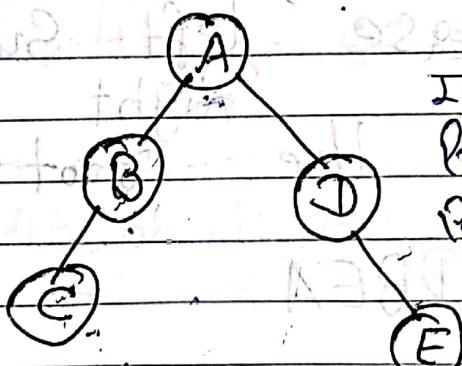

~~GT
marks.~~

Binary Tree Traversal

→ Traversing the tree means visiting each node exactly once.

L means move to the left child
 R " " " " Right "
 D " " the root/Parent mode.

Binary Tree Operations.

- (1) Creation of binary tree
- (2) Insertion of a node in the tree
- (3) Display of a binary tree.

Node can be represent like this

mode

Struct mode

struct mode {
 int data;
 mode *left;
 mode *right;

 };

Void Insert (mode *root,
 mode *New

{

char ch;

Point & char cohere to insert left/
right
of /d
, root->data)

```

Ch = getch();
if ((Ch == 'R') || (Ch == 'L'))
{
    if (root->right == NULL)
        root->right = New;
    else
    {
        if (root->left == NULL)
            root->left = New;
        else
            insert(root->left, New);
    }
}
else
{
    if (root->right == NULL)
        root->right = New;
    else
        insert(root->right, New);
}

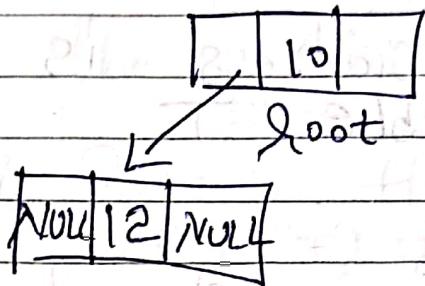

```

Initially root = NULL

Null	10	Null
------	----	------

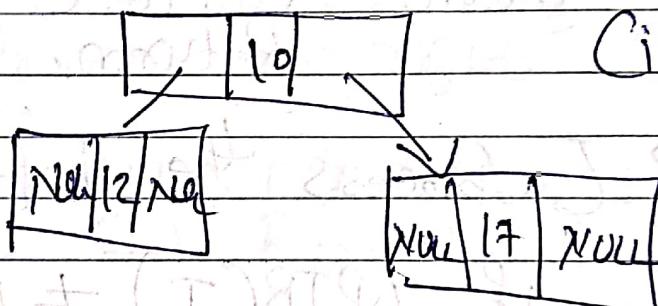

AS $\text{root} = \text{NULL}$, We will call NEW mode as Root.

i) Insertion of a node as a left child.

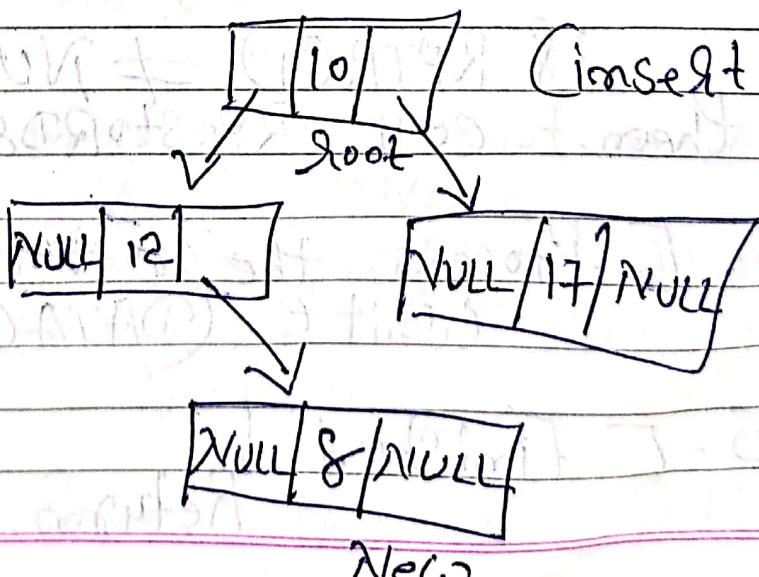

If $\text{root} \rightarrow \text{left} == \text{NULL}$
 $\text{root} \rightarrow \text{left} = \text{New}$

ii) Insertion of a node as a right child

If $\text{root} \rightarrow \text{right} == \text{NULL}$
 $\text{root} \rightarrow \text{right} = \text{New}$

Now if we want to insert node 8 as a right child of node 12 then

Insert ($\text{root} \rightarrow \text{left}$,
 $\text{New})$

~~Recursive~~ traversal(1) RPOSTORDER(T)

→ Root node address is given by Pointer variable T .

1. [Check for empty tree]

if $T = \text{NULL}$
then write ('EMPTY TREE')
Return.

2. [Process the left Subtree]

if $\text{LPTR}(T) \neq \text{NULL}$

then call $\text{RPOSTORDER}(\text{LPTR}(T))$

3. [Process the right Subtree]

if $\text{RPTR}(T) \neq \text{NULL}$

then call $\text{RPOSTORDER}(\text{RPTR}(T))$

4. [Process the root node]

write ($\text{DATA}(T)$)

5. [Finished]

Return.

(2) RINORDER (T)

1. [checks for empty tree]

if $T = \text{NULL}$

then write ('EMPTY TREE')

Return

2. [Process the left Subtree]

if $LPTR(T) \neq \text{NULL}$

then call RINORDER ($LPTR(T)$)

3. [Process the root node]

write ($\text{DATA}(T)$)

4. [Process the right Subtree]

if $RPTR(T) \neq \text{NULL}$

then call RINORDER ($RPTR(T)$)

5. [finished]

Return.

(3) RPREORDER (T)

1. [Process the root node]

if $T \neq \text{NULL}$

then write ($\text{DATA}(T)$)

else write ('EMPTY TREE')

Return

2. [Process the left Subtree]

if $\text{LPTR}(T) \neq \text{NULL}$
then Call RPREORDER ($\text{LPTR}(T)$)

3. [Process the right Subtree]

if $\text{RPT}(T) \neq \text{NULL}$
then Call RPREORDER ($\text{RPT}(T)$)

4. [finished]

Return.

(T) - 8303998 (E)

Leftmost child of T is E

LINK(T) = E

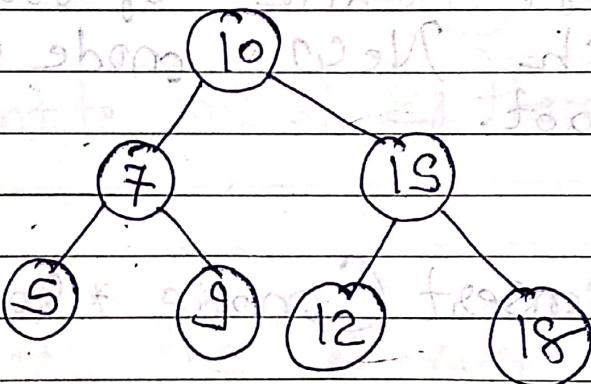

(T-DATA) = 8303998
(T-LINK) = E
(T-RIGHT) = 8215

* Binary Search Tree! -

~~CRITICAL
MARKS~~

- To make the Searching algorithm faster in a binary tree we will go for building the binary search tree.
- It is based on binary search algorithm.

→ Value of left subtree \leq Root node value \leq Right Subtree value.

* Various Operations that can be performed on binary search tree are:

- (1) Insertion of a node in BST.
- (2) Deletion , , ,
- (3) Searching Elements , ,
- (4) Display of binary tree.

(1) Insertion of a node in BST.

(1) Read the value for the node which is to be created and store it in a node called New.

(2) if ($\text{root} \neq \text{NULL}$) then $\text{root} = \text{New}$.

(3) Again read the next value of node created in New.

(4) If ($\text{New} \rightarrow \text{value} < \text{root} \rightarrow \text{value}$) then attach New mode as a left child of root otherwise attach New mode as right child of root.

Void insert (node *root, node *New)

if ($\text{New} \rightarrow \text{data} < \text{root} \rightarrow \text{data}$)

if ($\text{root} \rightarrow \text{left} = \text{NULL}$)

$\text{root} \rightarrow \text{left} = \text{New};$

else

insert ($\text{root} \rightarrow \text{left}$, New);

if ($\text{New} \rightarrow \text{data} > \text{root} \rightarrow \text{data}$)

if ($\text{root} \rightarrow \text{right} = \text{NULL}$)

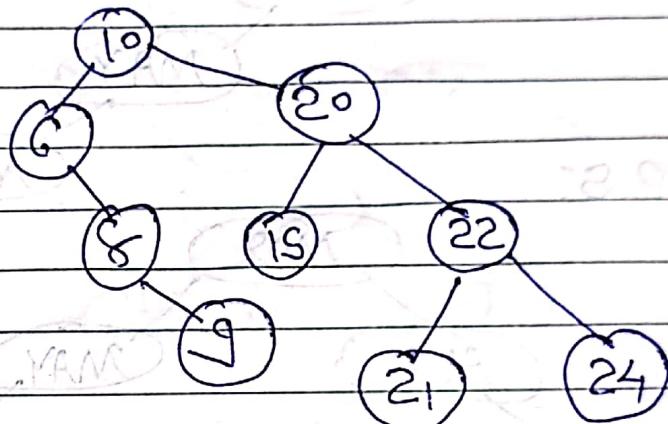

{ if ($\text{root} \rightarrow \text{right} == \text{NULL}$)

$\text{root} \rightarrow \text{right} = \text{New};$

else

insert ($\text{root} \rightarrow \text{right}$, New);

}

if we want to insert 23 then :

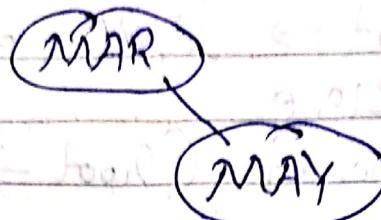

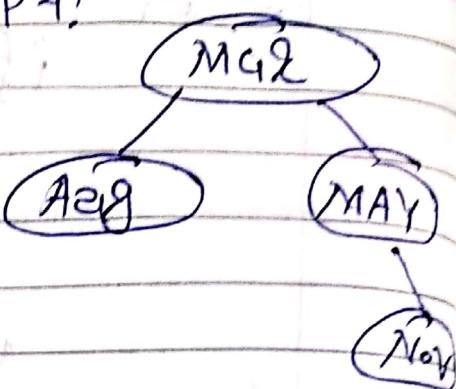

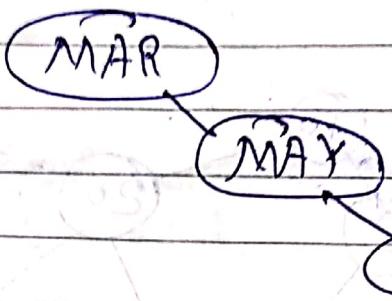

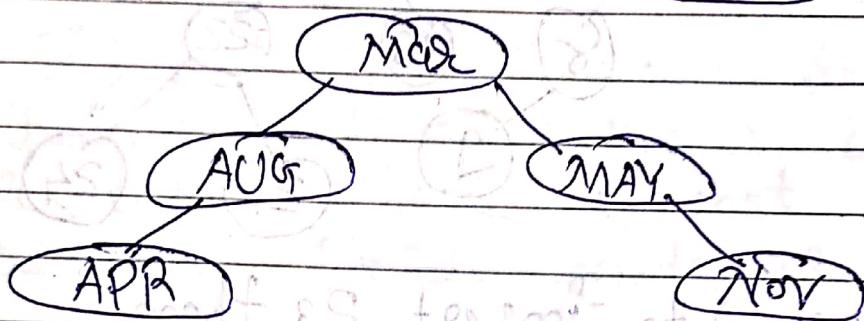

23

~~Ex!~~ Construct the binary Search tree from the following set of strings.

Step 11:

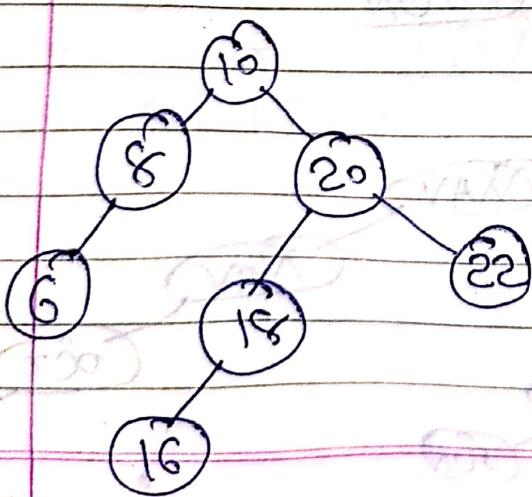

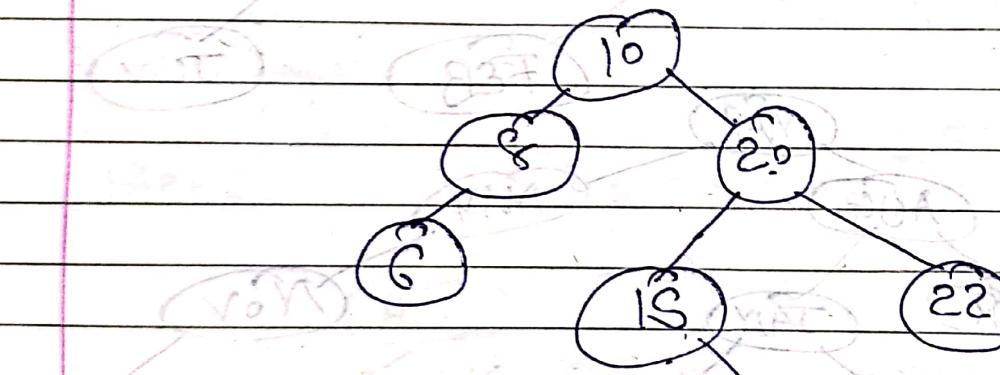

* Deletion of an element from the binary tree:

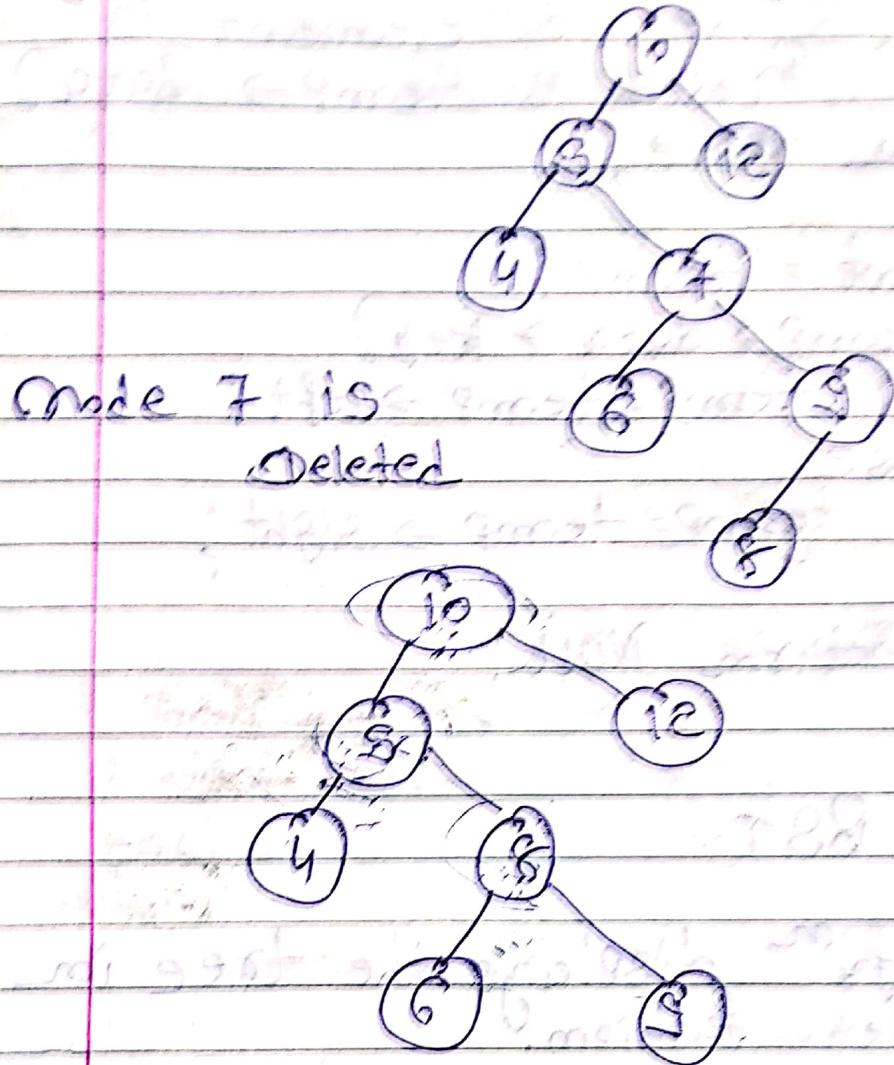

(1) Deletion of leaf node

(2) Deletion of node having one child

(3) The node having two children.

* Searching a node from BST.

```
node* Search(node* root, int key,  
            node** parent)
```

```
    node* temp;
```

```
    temp = root;
```

```
    while (temp != NULL)
```

```
{
```

```
    if (temp->data == key)
```

```
Printf("The %d element is
Present", temp->data);
return temp;
```

* Present = temp;
 if (temp->data > key)

temp = temp->left;

else

temp = temp->right;

} return NULL;

* Display BST

\Rightarrow This fn displays the tree in
 inorder fashion.

Void inorder(node *temp)

if (temp != NULL)

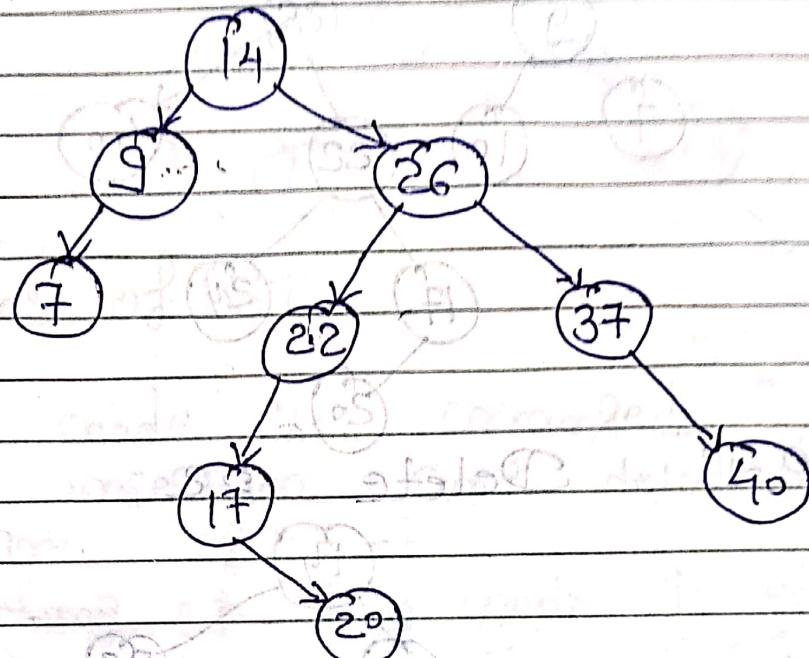

inorder(temp->left);

Printf("%d ", temp->data);

inorder(temp->right);

* Conversion of General Trees to Binary Trees!

- General trees are those tree in which there could be any number of nodes that can be attached as a child nodes.
- The number of subtrees for each node may be varying.

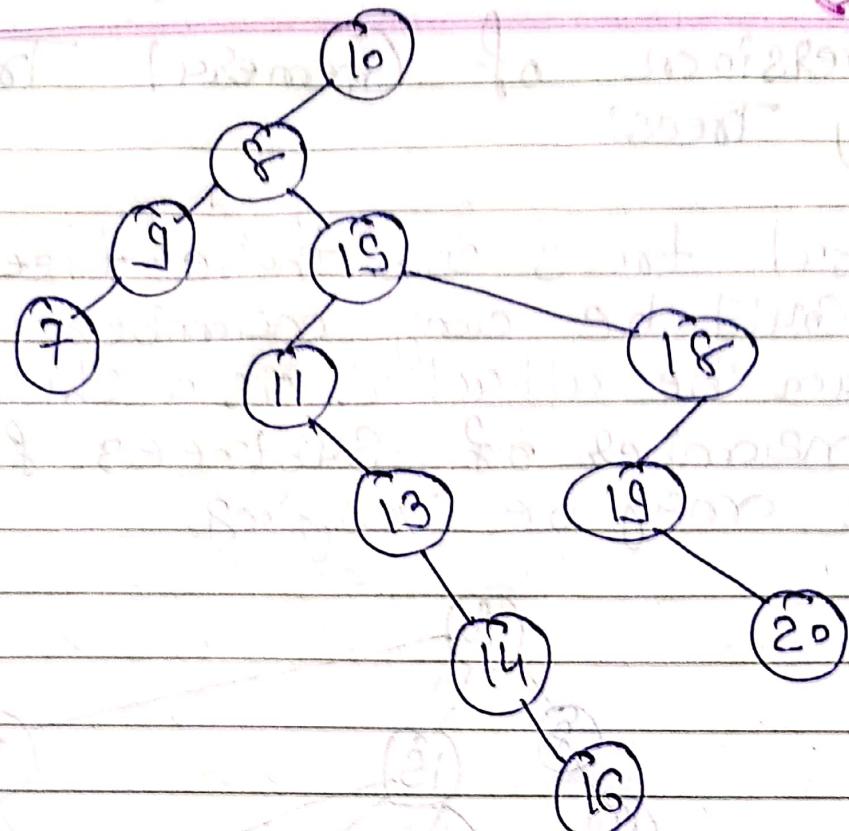

General Tree

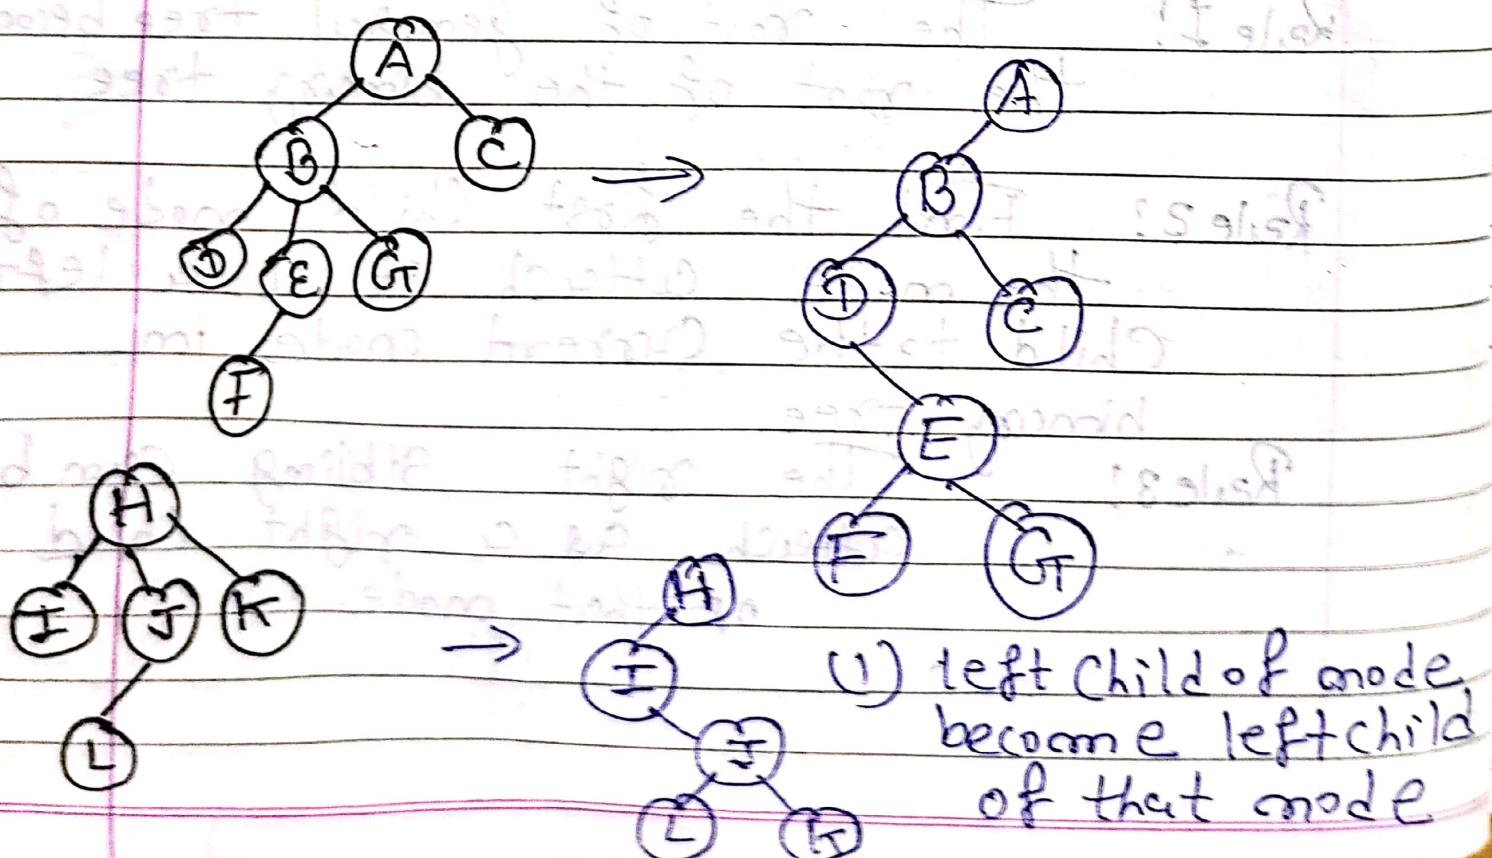

Rule 1! The root of general tree become the root of the binary tree.

Rule 2? Find the first child node of the mode attach it as a left child to the current mode in binary tree.

Rule 3! The right sibling can be attach as a right child of that mode.

~~Ex~~ Trace Procedure to convert following forest into binary tree.

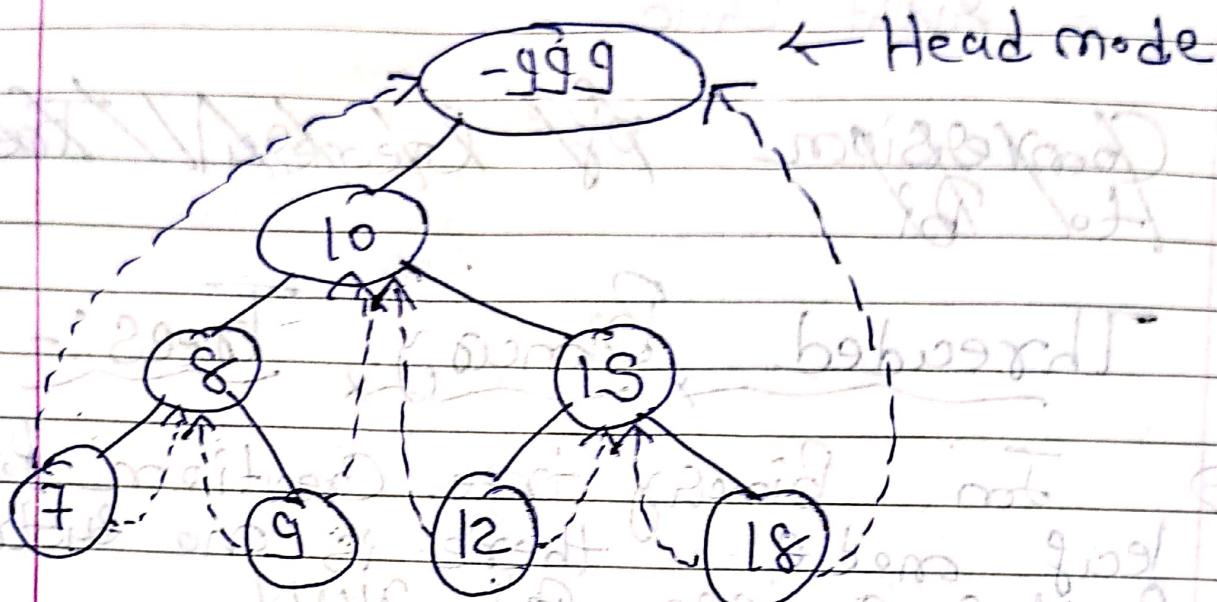

(2) The sibling of a node becomes its right child.

* Compression of General Trees to Bi

Threaded Binary Trees:-

- In Binary tree, Creation for the leaf mode there is no subtree further so we put NULL.
- It is wastage of memory So, to avoid NULL values in the mode we just set the threads which are actually the links to the Predecessor and Successor nodes.
- Three types of threading is Possible Inorder, Preorder and Postorder.
- We will discuss inorder threading.
- Here left thread should point to the Predecessor and right thread points to the Successor.
- Assume Head mode is starting mode and root mode of tree is attached to left of head mode.

* Applications of Trees!

- The purpose of binary tree is to have efficient retrieval of data.
- It is a useful data structure when we require to take two-way decisions.
- The use of binary tree is exploited by following data structure.
 - (1) BST
 - (2) Expression trees
 - (3) Threaded binary trees.
 - (4) Game tree.

* Concept of Balanced Trees

- Balanced trees are useful data structures that are useful to store the data at some specific location.

Def → A balanced tree is a rooted tree where each subtree of the root has equal number of nodes.

→ The height of such binary tree is $O(\log N)$

Many types of balanced tree is

- (1) Height balanced tree or AVL-tree
- (2) Splay tree
- (3) Red-black trees.
- (4) B-trees.

* AVL Trees:

Def. An empty tree is height balanced if T is a non-empty binary tree with TL and TR as its left and right subtrees. The T is height balanced if and only if

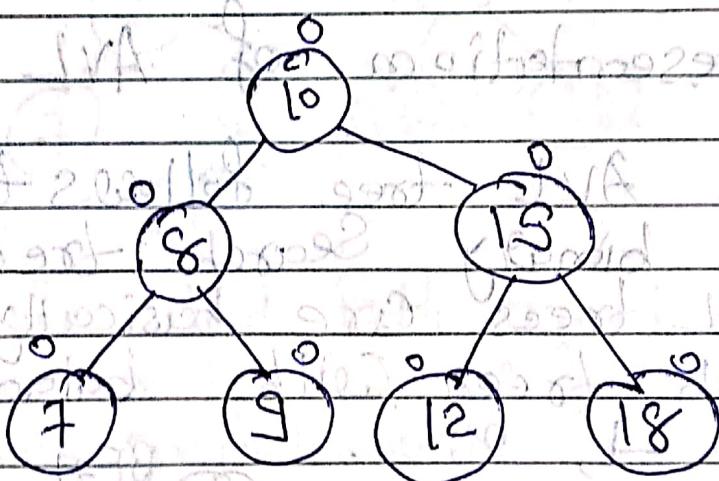

i) TL and TR are height balanced

ii) $|h_L - h_R| \leq 1$ where h_L and h_R are height of TL and TR.

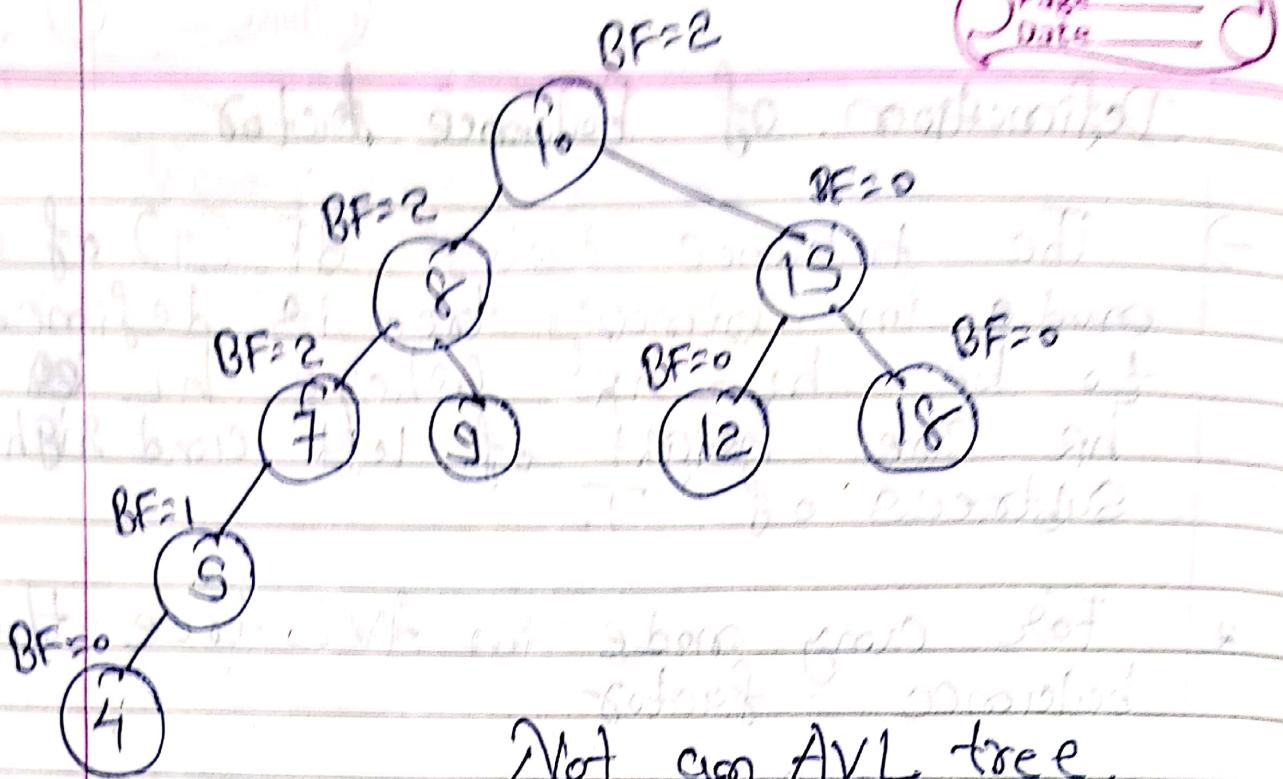

The idea of balancing a tree is obtained by calculating the balance factor of a tree.

Definition of Balance factor

- The balance factor $BF(T)$ of a node in binary tree is defined to be $h_L - h_R$ where h_L & h_R are height of left and right subtrees of T .
- * For any node in AVL tree the balance factor $BF(T)$ is $-1, 0$ or $+1$.

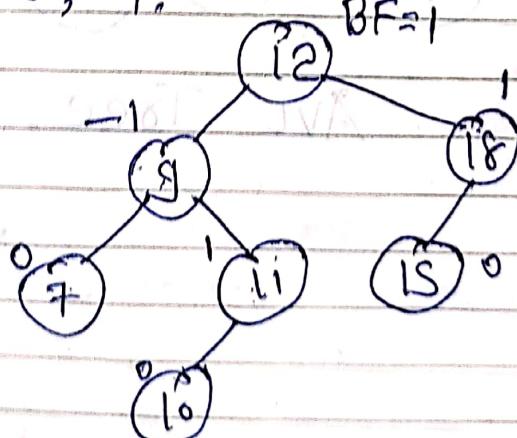

AVL Tree

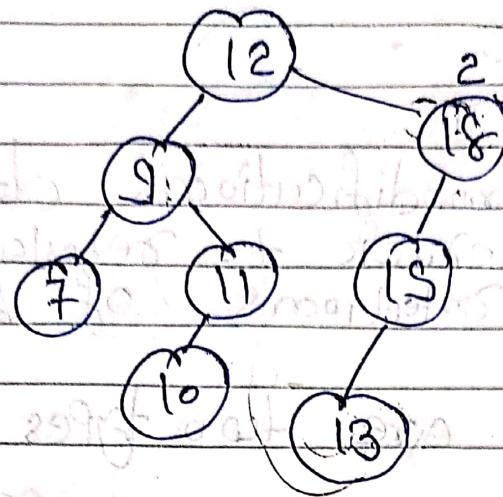

* Representation of AVL Tree.

→ The AVL tree follows the Property of binary Search tree. In fact AVL trees are basically binary Search tree with balance factor as -1, 0, 1.

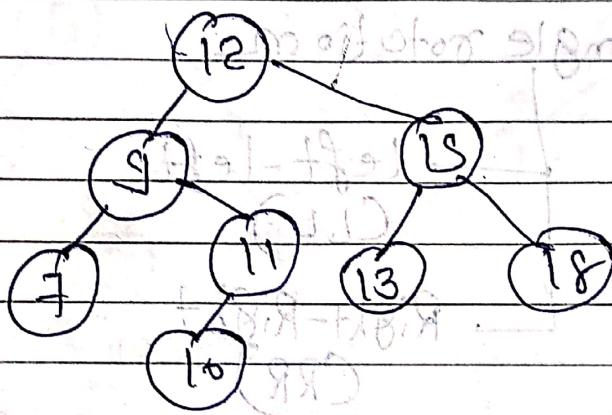

AVL tree.

Insert 13.

Property violated

So,

- mode on that Path need to be readjust
- means only the affected subtree is to be rebalanced.

Insertions

There are four different cases where rebalancing is required after insertion of new mode.

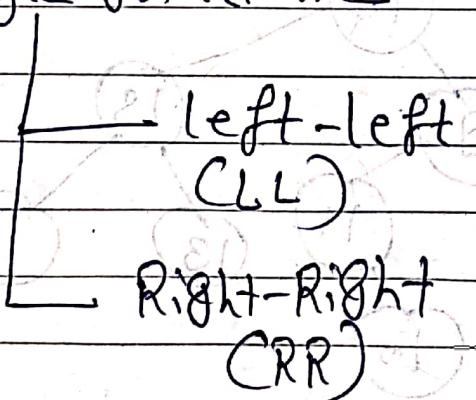

1. An insertion of new mode into left subtree of left child (LL)

2. CLR
3. CRL
4. CRR.

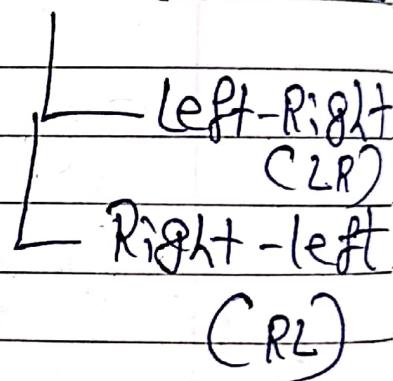

* Some modifications done on AVL tree in order to rebalance it is called rotations of AVL tree.

* There are two types of rotations.

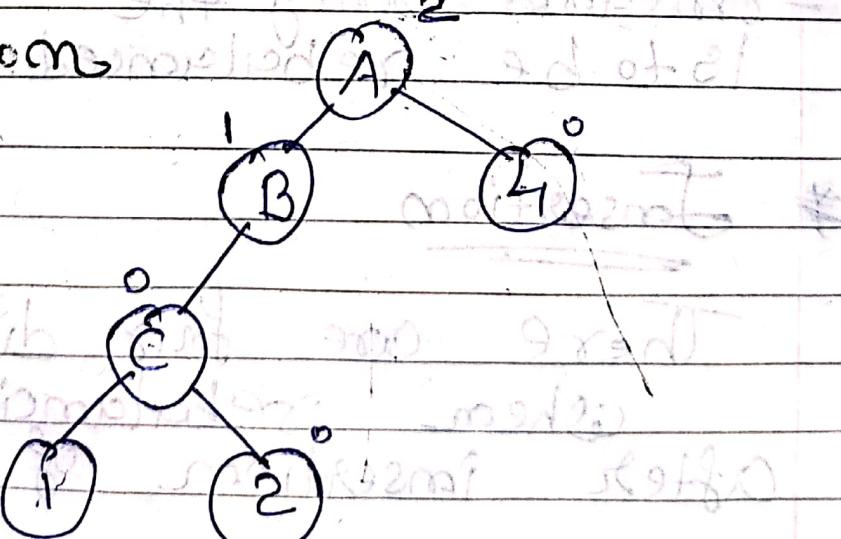

Single rotation

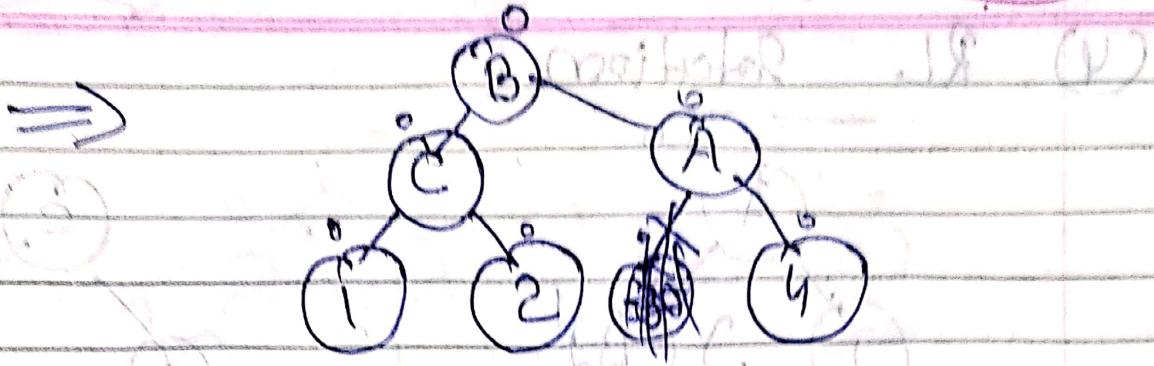

Double rotation

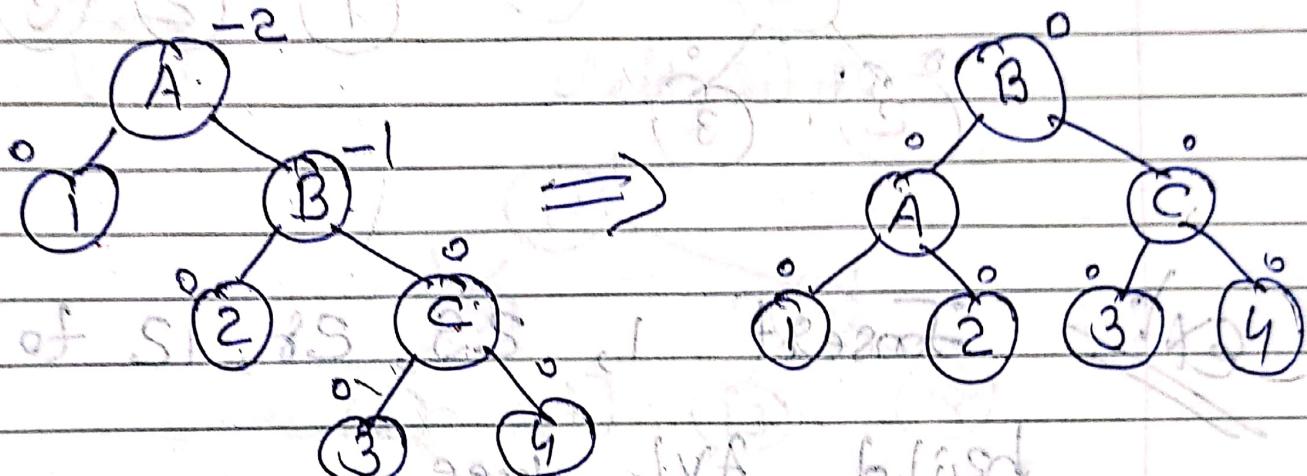

(1) LL rotation

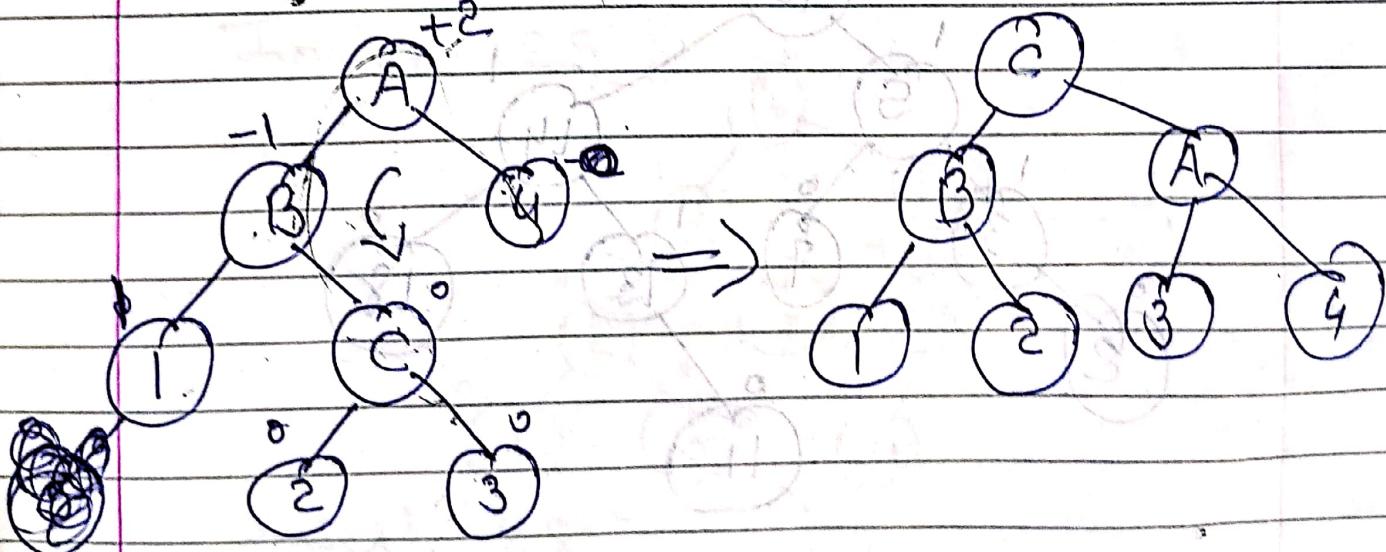

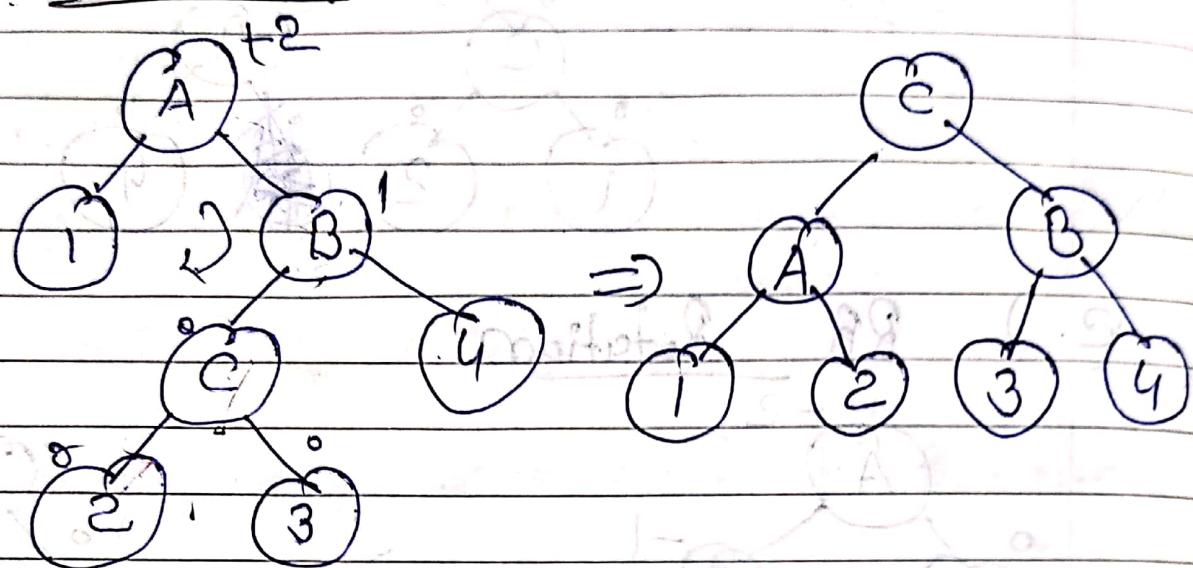

(E) RR Rotation

(3) LR rotation

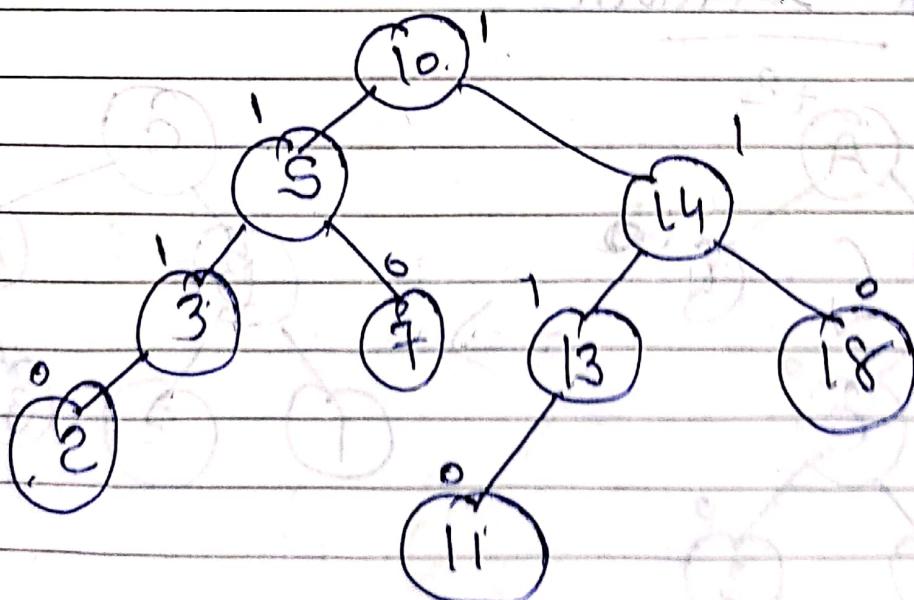

(4) RL Rotation

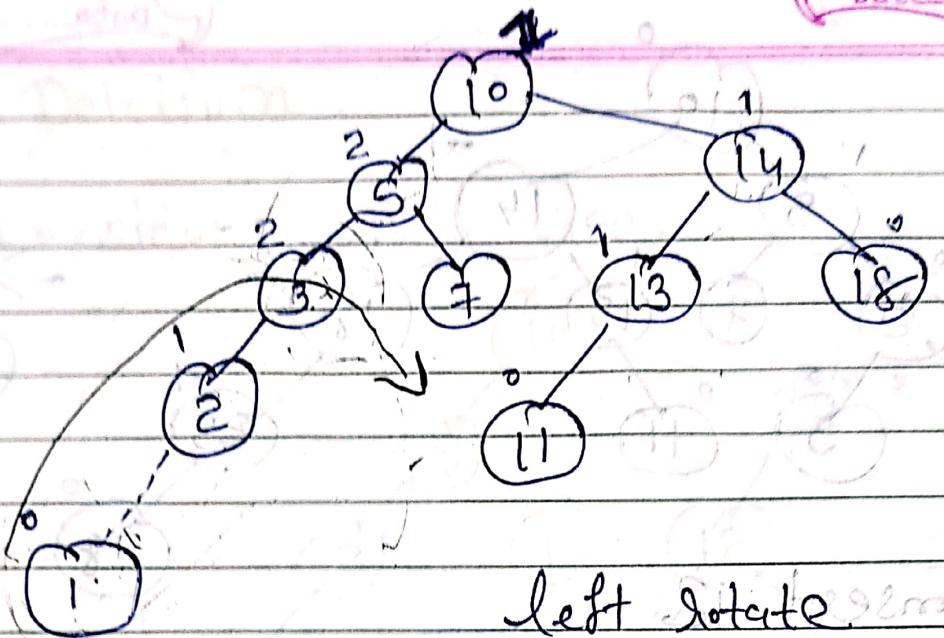

~~Ex:~~ Insert 1, 25, 28, 12 to

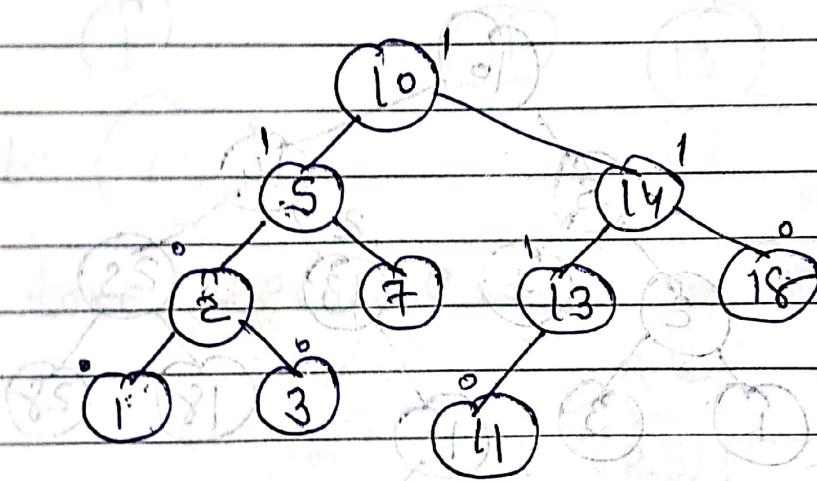

build AVL tree

insert 155

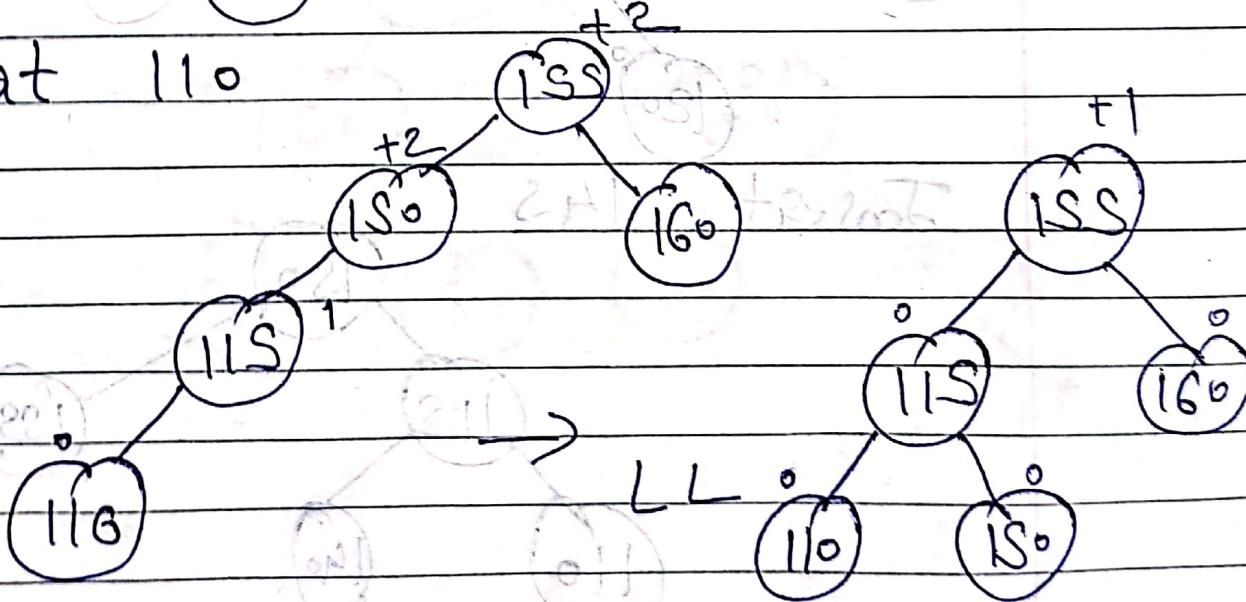

insert 160

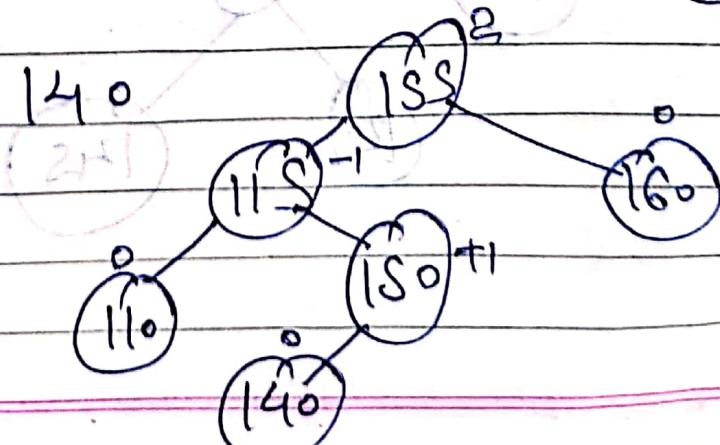

insert 115

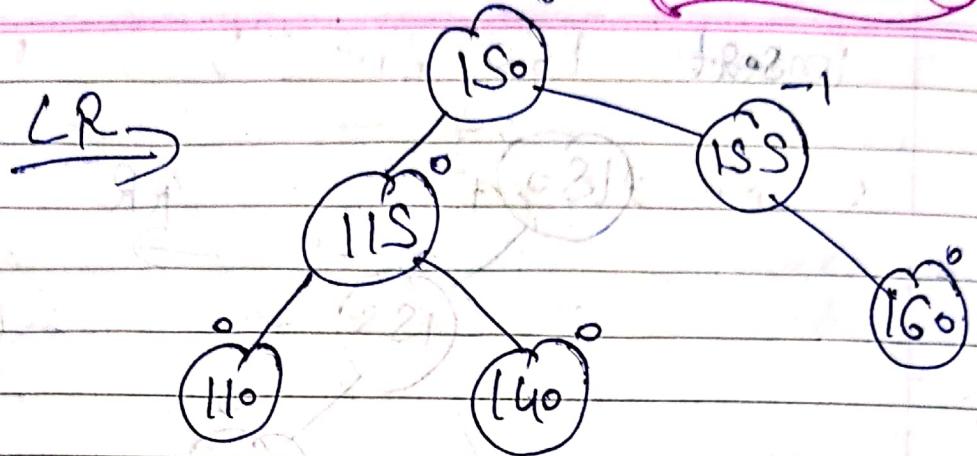

insert 110

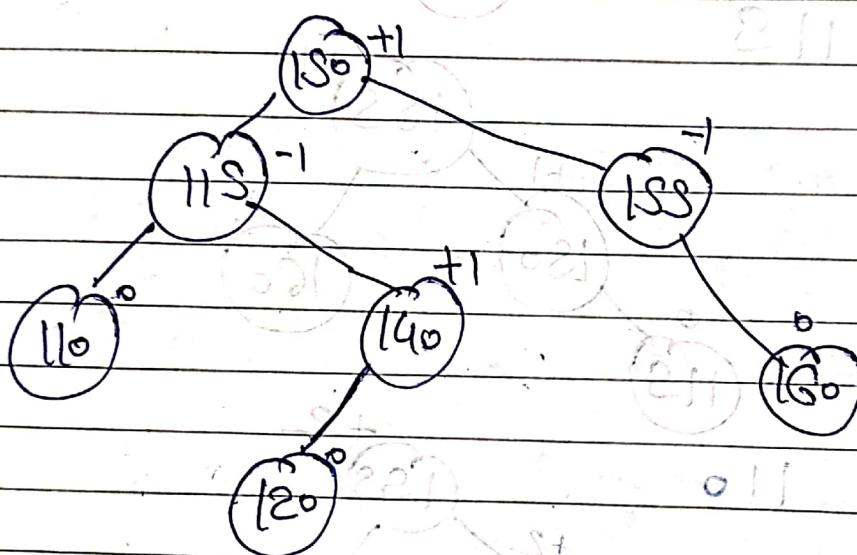

insert 140

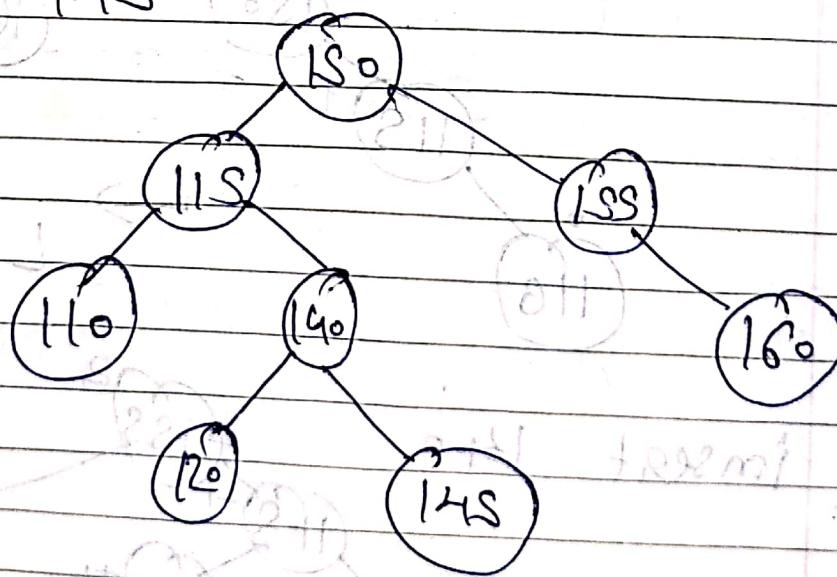

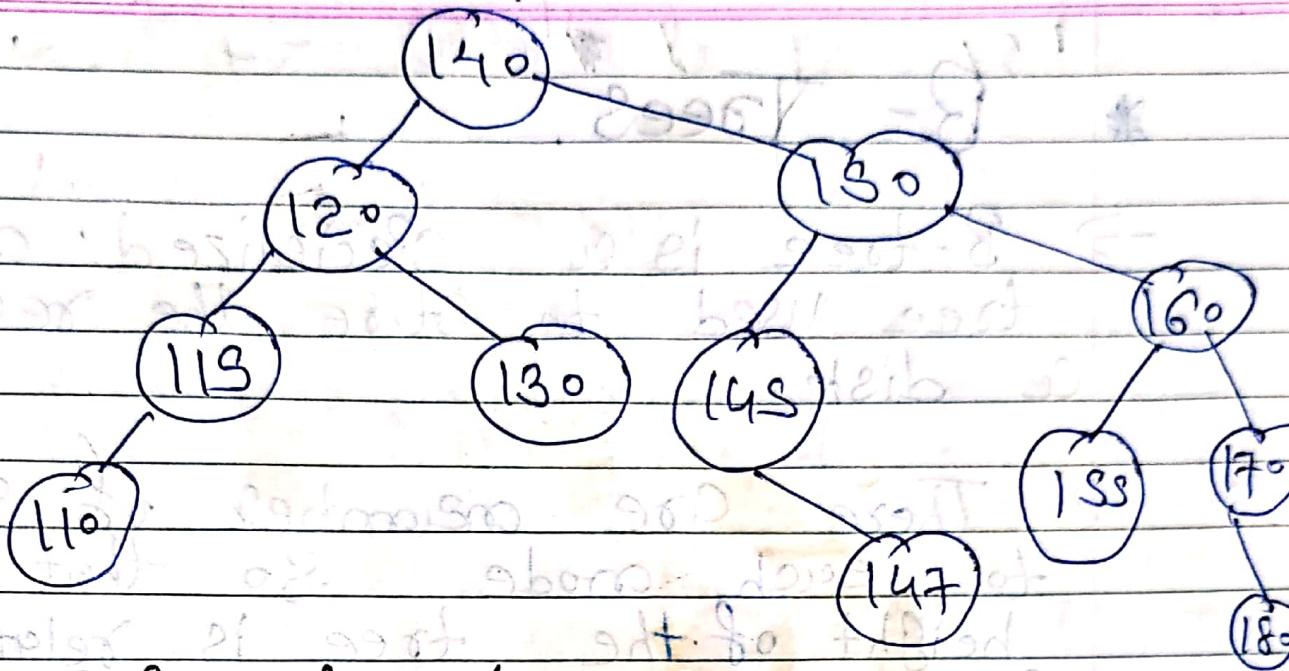

insert 120

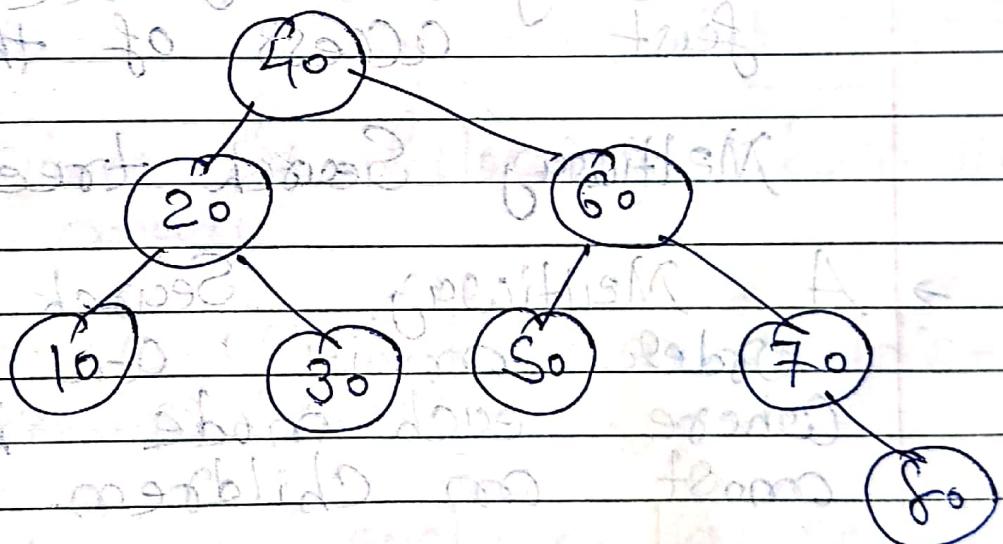

insert 145

~~Q1~~ Define AVL tree.

10, 20, 30, 40, 50, 60, 70, 80

* B-Trees.

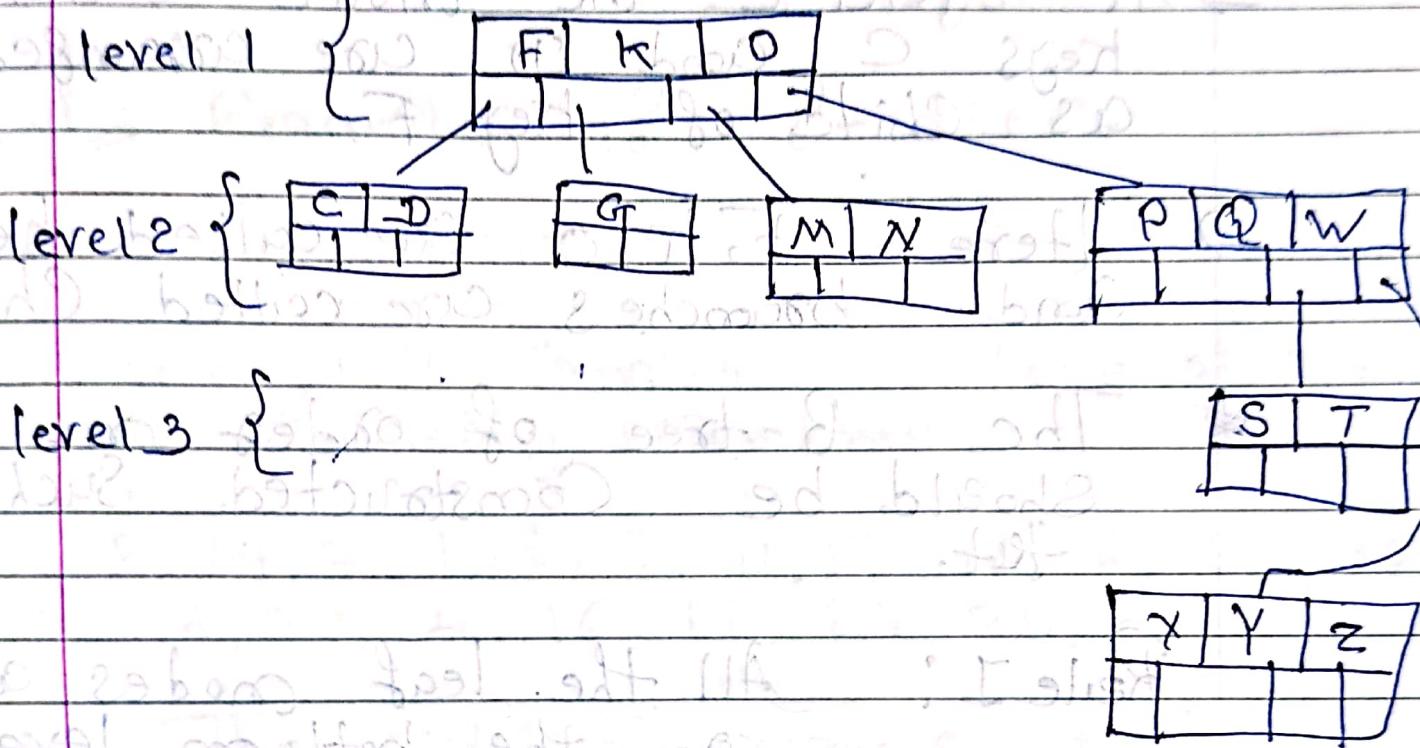

- B-tree is a specialized multiway tree used to store the record in a disk.
- There are number of subtree to each node. So that the height of the tree is relatively small.
- The goal of B-tree is to get fast access of the data.

Multicay Search tree:-

- A Multicay Search tree of order m is an ordered tree where each node has at most m children.
- if m number of children in a node then $(m-1)$ is the number of keys in the node.

~~Ex:~~

following is a tree of order 4.

From above fig. following observation
can be made.

- (1) The mode which has no children
Process (n-1) keys.
- (2) The key in each mode are in
ascending order.
- (3) For every mode Node. $\text{child}[0]$ has
only keys which are less than
mode. $\text{key}[0]$, $\text{child}[1]$ has only
keys which are greater than mode.
 $\text{key}[0]$.

→ The mode at level 1 has F, K and O as keys.

→ At level 2 the mode containing keys C and D are arranged as child of key F.

→ Here F, K, O are called keys and branches are called children.

* The B-tree of order m should be constructed such that:

Rule 1: All the leaf nodes are on the bottom level.

Rule 2: The root node should have atleast two children.

Rule 3: All the internal node except root node have atleast $\lceil \frac{m}{2} \rceil$ non-empty children. The ceiling is taken such that $\lceil \frac{m}{2} \rceil = 4$,

$$\lceil \frac{7}{2} \rceil = 4$$

$$\lceil \frac{9}{2} \rceil = 5$$

$$\lceil \frac{13}{2} \rceil = 7$$

~~Rule 4:~~ Each leaf node must contain atleast ceil (m/2) - 1 keys.

~~Ex:~~ Example of B-tree

~~* Insertion~~

We will construct B-tree of order 5 following members.

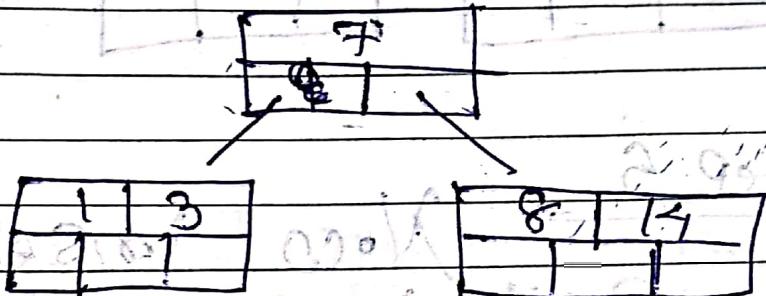

3, 14, 7, 1, 8, 5, 11, 17, 13, 6, 23, 12
20, 26, 4, 16, 18, 24, 25, 19

- The order 5 means at the most 4 keys are allowed.
- The internal node should have atleast 3 nonempty children and each leaf node must contain atleast 2 keys.

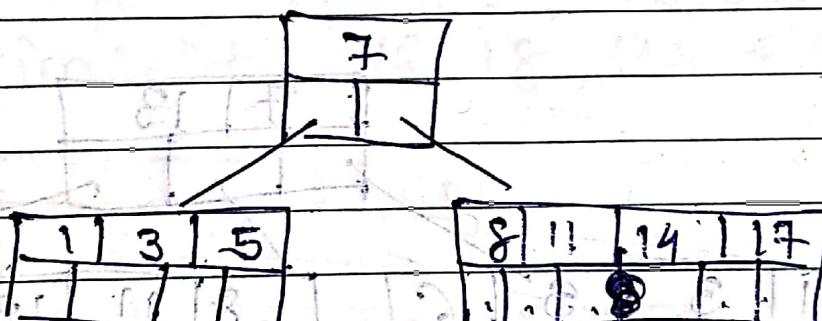

Step 1 Insert 3, 14, 7, 1 as follows

1	3	7	14
/			/

Step 2 if we insert 8 then we need to split the node 1, 3, 7, 8, 14. ut medium.

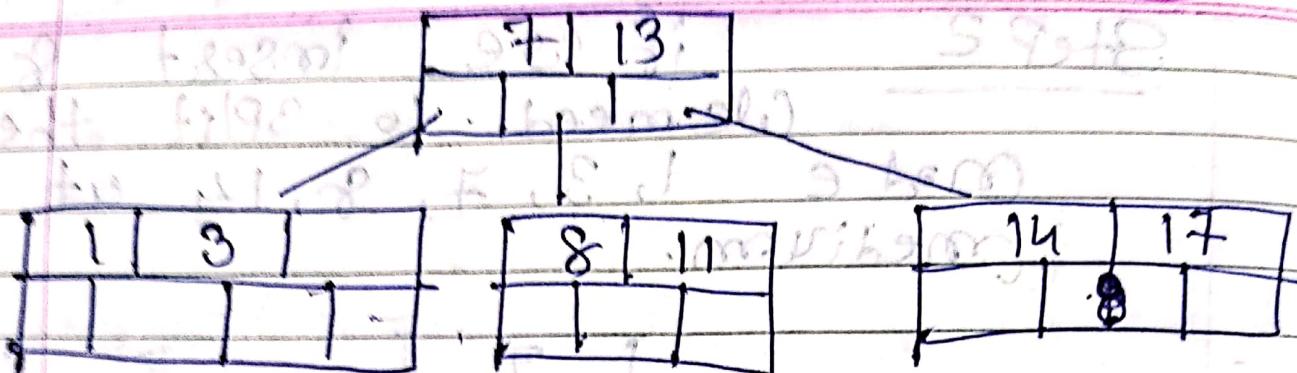

Step 3

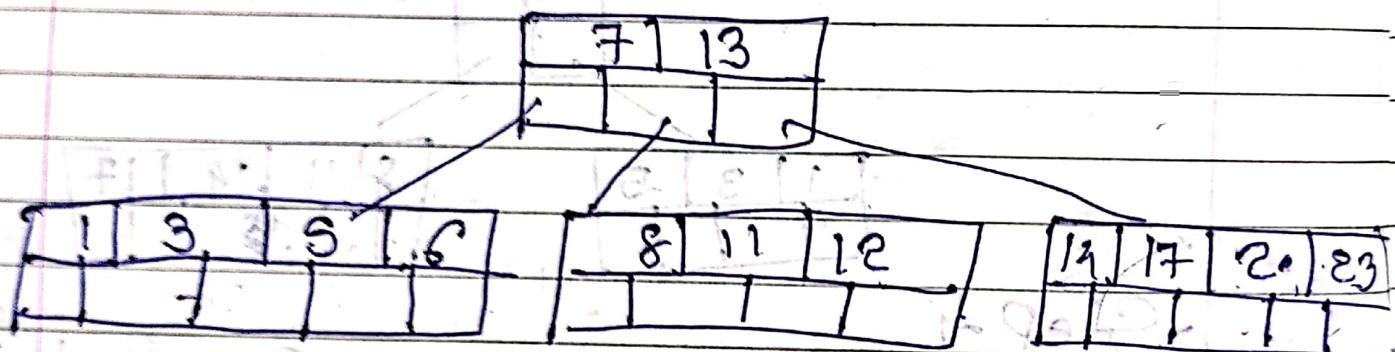

Step 4

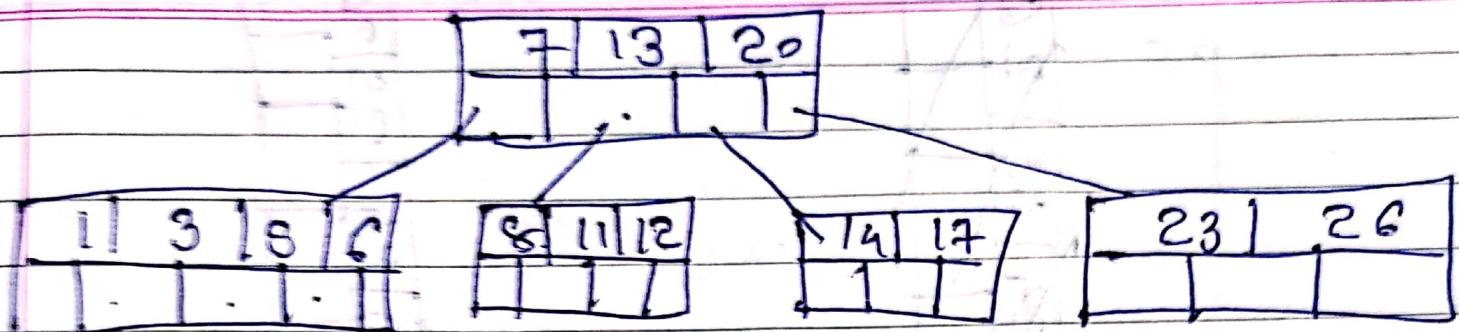

Now insert 13. But if we insert 13 then the leaf node will have 5 keys which is not allowed. So, 13, 14, 17 is split and medium mode 13 is removed.

Step 5.

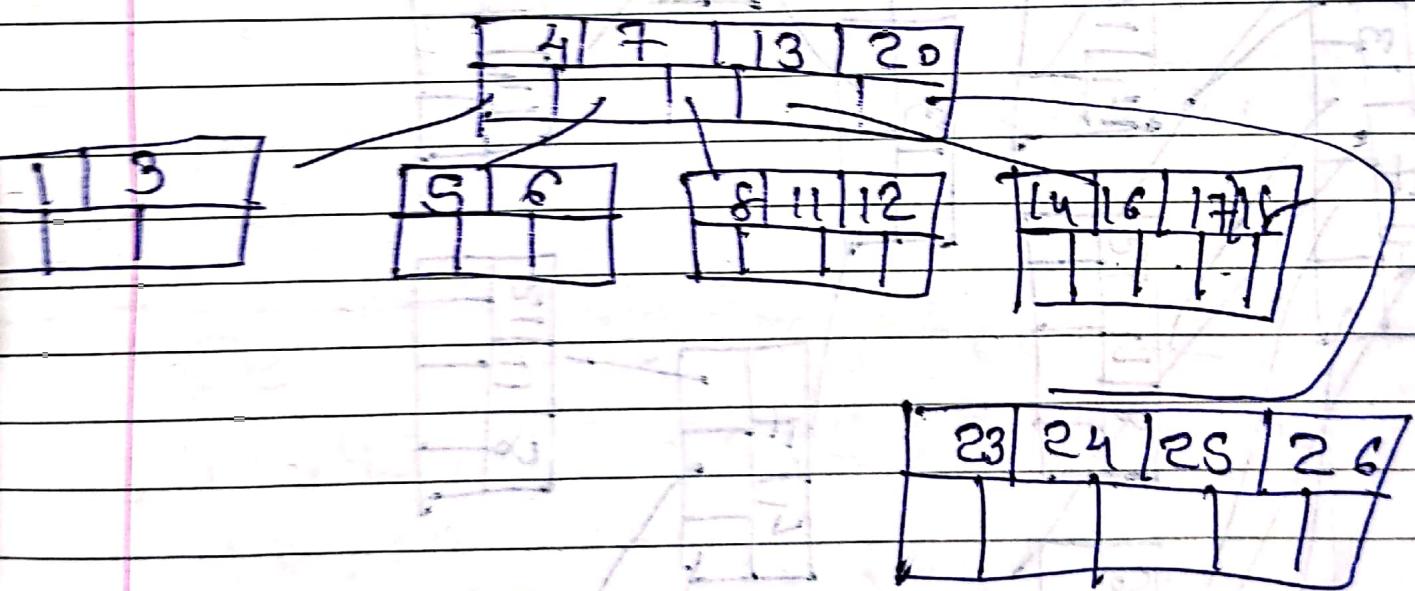

No CO insert 6, 23, 12, 20
Without any Split.

Step 6

The 26 is inserted to the rightmost leaf node. Hence 14, 17, 20, 23, 26 the mode is split and 20 will move up

Step 7

Insertion of mode 4 cause leftmost mode to split. The 1, 3, 4; 5, 6 causes key 4 to move up. Then insert 16, 18, 24, 25.

Step 8

Finally insert 19. Then 4, 7, 13, 18, 20 needs to be split. The ~~median~~ median 13 will be moved up from a root mode.
